Springer

Sustainable Development Goals Series

The **Sustainable Development Goals Series** is Springer Nature's inaugural cross-imprint book series that addresses and supports the United Nations' seventeen Sustainable Development Goals. The series fosters comprehensive research focused on these global targets and endeavours to address some of society's greatest grand challenges. The SDGs are inherently multidisciplinary, and they bring people working across different fields together and working towards a common goal. In this spirit, the Sustainable Development Goals series is the first at Springer Nature to publish books under both the Springer and Palgrave Macmillan imprints, bringing the strengths of our imprints together.

The Sustainable Development Goals Series is organized into eighteen subseries: one subseries based around each of the seventeen respective Sustainable Development Goals, and an eighteenth subseries, "Connecting the Goals", which serves as a home for volumes addressing multiple goals or studying the SDGs as a whole. Each subseries is guided by an expert Subseries Advisor with years or decades of experience studying and addressing core components of their respective Goal.

The SDG Series has a remit as broad as the SDGs themselves, and contributions are welcome from scientists, academics, policymakers, and researchers working in fields related to any of the seventeen goals. If you are interested in contributing a monograph or curated volume to the series, please contact the Publishers: Zachary Romano [Springer; zachary.romano@springer.com] and Rachael Ballard [Palgrave Macmillan; rachael.ballard@palgrave.com].

Preface

For Africa, the journey to achieving the aspirations of the African Union Agenda 2063 (Goal 1 on quality of life and well-being, and Goal 2 on health and nutrition) and the corresponding ambitions of the United Nation's Sustainable Development Goals (SDGs: SDG1 on Poverty alleviation, SDG2 on ending Hunger, etc.) must consider livestock production and productivity. Understanding the key types, availability, and use options of the livestock genetic resources in Africa is a first step in taking measures toward sustainable increased productivity and resilience in the face of a myriad of current and future challenges. In this connection, members of the executive committee of the African Animal Breeding Network (AABNet, https://www.animalbreeding-africa.org/index.html) started discussions in mid-2019 to explore the landscape and review key drivers and opportunities for establishing breeding goals for adapted and resilient African livestock to meet increasing demand for animal source food, the challenge of climate change, and environmental concerns. As discussions progressed, it became clear that the substantial information gaps on African livestock genetic resources could not be adequately covered, in the depth and breadth we had envisaged, in a single review paper, and the idea to write this book on "African livestock genetic resources and sustainable breeding strategies" was born, and the writing started in earnest in late 2020 involving 83 contributing authors—professionals and experts from animal science, animal breeding, genetics, genomics, and other science disciplines—from 24 countries.

Authored by African livestock professionals representing a wide range of disciplines and focused on an examination of efforts toward understanding indigenous African livestock, their uses and systems of production, improvement challenges, and achievements made to date, this book presents a rich resource, across livestock species, for formulating technical, institutional, and policy interventions going forward and that leverage on rapidly changing technologies and responds to evolving human nutritional needs and other trends.

For thousands of years, natural selection and human activities have generated genetically diverse breeds of domesticated farm animals, which can significantly contribute to the livelihoods of millions of present-day Africans. Indeed, they are a treasure trove. Africa's indigenous livestock are particularly hardy and well-adapted to local production contexts, having developed adaptations to the continent's diverse climatic conditions and environmental pressures. Despite the wealth of desirable genetic traits, some of Africa's

iconic and lesser-known livestock are disappearing at an alarming rate. Despite the increasing recognition of the benefits of this diversity, little has been done to understand and optimally harness the full potential of these genetic resources. This book catalogues the main farm animal genetic resources (cattle, sheep, goat, pig, chicken, dromedary, horse, donkey, buffalo, turkey, duck, and geese) and some non-conventional animal genetic resources (frog, rabbit, snail, and honeybee) in Africa and the opportunities that can be leveraged with available technologies and knowledge for achieving rapid genetic gain and improved productivity. While the structure of the chapters differ considerably, they cover five broad areas in the context of animal genetic resources in Africa: their characterization (to understand the unique genetic composition of what we have, where it might have originated from, and its present-day distribution); conservation; use (efforts and approaches to enhance sustainable utilization, focusing on improving production and productivity, and product quality to meet evolving human needs); technological support (available technological developments that support sustainable livestock improvement); and the institutions and institutional arrangements needed to support their characterization, conservation, and sustainable use.

This book is the first to present as one source, the diversity and uniqueness of African farm animal genetic resources, and the possibilities that new technologies present, which will give a better appreciation of the existing resources to a wide range of users. It is a valuable manual for students, professors, researchers, animal science professionals, livestock farmers and farmer organizations, civil society organizations, non-governmental organizations, business professionals, government agencies, including policymakers, the international development community, and anyone who seeks to understand the uniqueness of African livestock genetic resources, production systems, and strategies for sustainable improvement for the African environment.

Contents

Part I African Livestock Production Systems and Genetic Resources

1 An Overview of African Livestock Genetic Resources and Improvement Strategies 3
Eveline M. Ibeagha-Awemu, Sunday O. Peters, Appolinaire Djikeng, and John E. O. Rege

2 African Livestock Production Systems: The Past, Present and the Projected Future 13
Eveline M. Ibeagha-Awemu, Richard Osei-Amponsah, and Martha N. Bemji

3 The History, Geography, and Characteristics of Indigenous African Taurine Cattle 65
John E. O. Rege, Chi L. Tawah, Isidore Houaga, and Eveline M. Ibeagha-Awemu

4 The History, Geography, and Characteristics of African Zebu, Zebu–Taurine Derivatives, and Well-Established Exotic Cattle Breeds 117
John E. O. Rege, Chi L. Tawah, Donald R. Kugonza, Mizeck G. G. Chagunda, Isidore Houaga, Oluyinka Opoola, and Eveline M. Ibeagha-Awemu

5 African Goat Genetic Resources, Diversity and Unique Features 185
Moses Okpeku, Martha N. Bemji, Isidore Houaga, Khaled Fantazi, Liveness J. Banda, Timothy Gondwe, Sebastine Chenyambuga, Sahar A. Elnahta, Doctor M. N. Mthiyane, Shumuye Belay, Tadelle Dessie, Taiye S. Adewumi, and Oliver Hanotte

6 African Sheep Genetic Resources, Diversity and Unique Features 239
Martha N. Bemji, Semir B. S. Gaouar, Abdelkader Ameur Ameur, Fatima Z. Belharfi, Isidore Houaga, and Anne W. T. Muigai

7 African Domestic Poultry Genetic Resources, Diversity, and Unique Features 327
Tadelle Dessie, Christian K. Tiambo, Liveness J. Banda, Raman A. Lawal, Sheila C. Ommeh, Timothy Gondwe, Esatu Wondmeneh, Matthew A. Adeleke, and Olivier Hanotte

8 Pig Genetic Resources of Africa 357
Richard Osei-Amponsah and Wilson S. Kaumbata

9 African Dromedary Genetic Resources, Diversity and Breeding Systems 395
Semir B. S. Gaouar, Imane Meghelli, Zoubeyda Kaouadji, Félix Meutchieye, and Djalel E. Gherissi

10 African Donkey Genetic Resources, Diversity and Breeding Strategies 451
Martha N. Bemji, Eveline M. Ibeagha-Awemu, Abdelkader Ameur Ameur, Albano Beja-Pereira, Madani Labbaci, Liveness J. Banda, and Semir B. S. Gaouar

11 African Horse Genetic Resources and Breeding Strategies for African Input Systems 497
Djalel E. Gherissi, Ginette Aumassip-Kadri, Mohammed E. A. Benhamadi, Félix Meutchieye, Yassine H. Jamali, and Semir B. S. Gaouar

12 African Water Buffalo Genetic Resources, Diversity, and Unique Features 593
Sahar S. E. Ahmed, Amal A. M. Hassan, Ibrahim A. H. Barakat, and Hassan M. Al Ashmaoui

13 Nonconventional Animal Genetic Resources, Diversity, and Unique Features 619
Kingsley A. Etchu, Abdelkader Ameur Ameur, M. Chahbar, Félix Meutchieye, Annick N. Enangue Njembele, Gerald C. Tasse Taboue, and Semir B. S. Gaouar

14 Contributions of African Livestock Production Systems to Greenhouse Gas Emissions and Global Warming in the Face of Climate Change 675
Mizeck G. G. Chagunda, Kingsley A. Etchu, Kwamboka Tirimba, and Okeyo Mwai

Part II Opportunities for Improved Utilization of African Livestock Genetic Resources

15 Defining Breeding Goals and Breeding Strategies for Improving Livestock Under Various Production Systems in Africa: Concept and Brief Overview 691
Raphael Mrode, David A. Mbah, and Julie M. K. Ojango

16 Defining Breeding Goals and Breeding Strategies for Improving the Productivity of Cattle Breeds and Buffaloes in African Production Systems 705
Raphael Mrode, David A. Mbah, Chi L. Tawah, Julie M. K. Ojango, Sunday O. Peters, Eveline M. Ibeagha-Awemu, Oluyinka Opoola, Isidore Houaga, Richard Osei-Amponsah, Moses Okpeku, and John E. O. Rege

17 Breeding Goals and Strategies for Improving Small Ruminant Productivity in African Input Systems 759
Julie M. K. Ojango, Richard Osei-Amponsah, Isidore Houaga, Timothy Gondwe, Moses Okpeku, and Donald R. Kugonza

18 Defining Breeding Goals and Breeding Strategies for Chicken Production Systems in Africa 785
Sunday O. Peters, Michael O. Ozoje, Adeyemi S. Adenaike, Blaise A. Hako Touko, Christian K. Tiambo, Matthew A. Adeleke, Oluyinka Opoola, and Tadelle Dessie

19 Defining Breeding Goals and Breeding Strategies for Pigs in Various African Production Systems 819
Donald R. Kugonza and Richard Osei-Amponsah

Part III Leveraging Modern Technologies for Improved Utilization of African Livestock Genetic Resources

20 Role of Modern Technologies for Sustainable Genetic Improvement of African Livestock 851
Eveline M. Ibeagha-Awemu, Sunday O. Peters, Martha N. Bemji, Jean M. Feugang, Richard Osei-Amponsah, Daniel Trocmé, and Raphael Mrode

21 The Role of Modern Technologies for Improving the Production Environment of Livestock in Africa 909
Eveline M. Ibeagha-Awemu, Faith A. Omonijo, Martha N. Bemji, Obioha Duranna, Iliya D. Kwoji, Michael O. Ozoje, and Richard Osei-Amponsah

22 Prospects for Utilization of Modern Technologies for Cattle Improvement in Africa 991
Sunday O. Peters, Eveline M. Ibeagha-Awemu, Iliya D. Kwoji, Raphael Mrode, Michael O. Ozoje, David A. Mbah, Isidore Houaga, Moses Okpeku, Peter O. Fayemi, Daniel Trocmé, Oluyinka Opoola, and Matthew A. Adeleke

23 Prospect of Modern Technologies for Poultry Improvement in Africa 1021
Victor E. Olori, Sunday O. Peters, and Matthew A. Adeleke

24 Prospect for Utilization of Modern Technologies for Small Ruminant and Pig Improvement in African Input Systems: Case Studies 1049
Jean M. Feugang, Othman E. -M. Othman, Wilson Nandolo, Donald R. Kugonza, and Richard Osei-Amponsah

Part IV Conservation of African Livestock Genetic Resources

25 Conservation and Management of Animal Genetic Resources in the Context of African Livestock Production Systems: The Case for In Situ and Ex Situ Conservation 1071
Jean M. Feugang, Richard Osei-Amponsah, John E. O. Rege, Khaled Fantazi, Christian K. Tiambo, Felicien Shumbusho, Isidore Houaga, Derradji Harek, Notsile H. Dlamini, and Semir B. S. Gaouar

26 Economic Considerations and Framework of Conservation of African Animal Genetic Resources 1091
Wilson Kaumbata, Maria Wurzinger, and John E. O. Rege

Part V Institutional Arrangements and Enabling Environment for Enhanced Utilization of African Livestock Genetic Resources

27 Capacity Strengthening of Animal Genetic Improvement Education in Africa 1109
Samuel E. Aggrey, Richard Osei-Amponsah, Donald R. Kugonza, Raphael A. Mrode, Romdhane Rekaya, and John E. O. Rege

28 Capacity Building in Livestock Breeding and Genetic Improvement in Achieving UN Sustainable Development Goals for Africa 1123
Christian K. Tiambo, Oluyinka Opoola, Moses Okpeku, Isidore Houaga, Blaise A. Hako Touko, and Tadelle Dessie

29 Harnessing Multi-Country Cooperations, Initiatives, Facilities, and Technologies for Advancing Livestock Genetic Improvement in Africa 1149
Ntanganedzeni O. Mapholi, Cuthbert Banga, Raphael Mrode, Oluyinka Opoola, Isidore Houaga, Lucy T. Nesengani, and Eveline M. Ibeagha-Awemu

30 Policies, Frameworks, Strategies, and Action Plans for Conservation and Sustainable Use of African Animal Genetic Resources 1185
John E. O. Rege and Mure Agbonlahor

31 Resourcing and Institutional Arrangements to Deliver Sustainable Animal Genetic Improvement in Africa 1233
Eveline M. Ibeagha-Awemu, Victor Olori, Ismail Muritala, Olubunmi I. Duduyemi, Mizeck G. G. Chagunda, and John E. O. Rege

Fig. 11.27 The South African Nooitgedacht stallion named Mac. (FAO *2002*)In 1958, the birth of the stallion Mac marked a pivotal moment in the development of the Nooitgedacht horse breed. Mac exemplified the ideal general-purpose horse sought by project managers, displaying key physical traits such as a strong shoulder, well-muscled back, and robust legs with hard hooves. Additionally, Mac embodied the distinctive characteristics of the Nooitgedacht breed, with his small pointed ears, pronounced brows, and straight to slightly concave profile. This iconic horse left a lasting legacy in the breed's evolution (Photo: Landbouweekblad) 536

Fig. 12.2 Phylogeny of Bubalus based on complete mitochondrial genomes. The tree was reconstructed with MrBayes software using the 118 mitogenomic haplotypes of Bubalus identified in our alignment of 16,356 nucleotides. The tree was rooted with Syncerus (not shown). Haplogroups showing more than 0.5% of nucleotide divergence are highlighted by different colored rectangles, and those found in the swamp buffalo are named SBa to SBe (the name of the haplotype is followed by a dash and a number when the same haplotype was found in least two individuals). Among the 29 mitogenomes of Egyptian river buffalo, the 21 samples collected from North are indicated in red, whereas the eight samples collected from South are indicated in green. The four mitogenomes of river Buffalo assembled using SRA data available in GenBank are named with the SAMN accessions. For nodes supported by bootstrap percentage (BP) _ 90 in the RAxML analysis (see details in Material and Methods), the two values correspond to the posterior probability (PP calculated using MrBayes software, left of the slash) and BP (right of the slash). An asterisk is used when both MrBayes and RAxML analyses provided maximal support values, i.e., PP ¼ 1 and BP ¼ 100, respectively. No information was provided for nodes supported by BP <90. Fig. 20.4 Genome editing platforms and mechanisms for DSB repair with endogenous DNA. Genome editing nucleases (ZFNs, TALENs and CRISPR/Cas9) induce DSBs at targeted sites. DSBs can be repaired by NHEJ or, in the presence of donor template, by HDR. Gene disruption by targeting the locus with NHEJ leads to the formation of indels. When two DSBs target both sides of the amplification or insertion, a therapeutic deletion of the intervening sequences can be created, leading to NHEJ gene correction. In the presence of a donor-corrected HDR template, HDR gene correction or gene addition induces a DSB at the desired locus. DSB double-stranded break, ZFN zinc-finger nuclease, TALEN transcription activator-like effector nuclease, CRISPR/Cas9 clustered regularly interspaced short palindromic repeat associated 9 nuclease, NHEJ nonhomologous end-joining and HDR homology-directed repair. Part I

African Livestock Production Systems and Genetic Resources

1 An Overview of African Livestock Genetic Resources and Improvement Strategies

Eveline M. Ibeagha-Awemu, Sunday O. Peters, Appolinaire Djikeng, and John E. O. Rege

Abstract

This book is the first comprehensive text that presents the rich livestock genetic resources in Africa in one volume. This introductory chapter summarizes the materials covered in the book. It introduces the various topics covered and serves as a guide to topics of interest.

Keywords

African indigenous livestock breeds · Rich genetic diversity · Improved utilization and modern technologies · Institutional arrangements · Conservation of African livestock genetic resources

1.1 Introduction

Animal genetic resources (AnGR), and in particular, those used for food and agriculture, are important components of global biodiversity and

E. M. Ibeagha-Awemu et al. (eds.), *African Livestock Genetic Resources and Sustainable Breeding Strategies*, Sustainable Development Goals Series, https://doi.org/10.1007/978-3-031-92076-9_1

key contributors to human survival through the provision of critical components of nutrition and diverse social, cultural, economic, and environmental sustainability needs. An estimated 8800 breeds and strains across animal species are of crucial significance for food and agriculture (FAO 2021, 2023a). Africa has the richest diversity in terms of the number of breeds of cattle, goat, and dromedary. Africa has the second highest number of sheep, chicken, rabbit, and donkey breeds compared to other regions of the world (FAO 2021, 2023a; AU-IBAR 2019) (Table 1.1). Within Africa, cattle are the most dominant in terms of the number of breeds (692), followed by sheep (363), chicken (329), and goat (289) (Table 1.2). This high number of livestock breeds is an invaluable treasure that is critically important to the socioeconomic well-being of Africans. In particular, African indigenous livestock breeds (Table 1.2) exhibit unique and rare adaptive characteristics carefully crafted by years of natural and artificial selection for adaptation to local environmental and production conditions.

Africa's livestock accounts for one-third of the global livestock population (AU-IBAR 2016) and, on average, 40% of the national agricultural GDP, ranging from 10% to 80% in individual countries (Panel, M. M 2020). The demand for animal-source food is projected to increase due to population growth, increased incomes, and urbanization. These demographics point to a trend wherein livestock will be increasingly important in Africa. Being intricately interwoven with the livelihood of farming communities on the continent, livestock has the potential to deliver both the socioeconomic transformation and food security needs of Africa as envisioned in the African Union (AU) Malabo Declaration on Accelerated Agriculture Growth and Transformation, which is a key part of the framework of the AU Agenda 2063, the United Nations Sustainable Development Goals (UN-SDGs), the livestock development strategy for Africa (LiDeSA), and other frameworks and initiatives that cover agriculture and food and nutrition secuirty (AU-IBAR 2015; AU 2015; FAO 2015). This is especially so because, in Africa, livestock farming does not only provide poor people with food, income, traction, and fertilizer but also acts as a catalyst that transforms subsistence farming into income-generating enterprises, allowing poor households to enter the market economy. Indeed, livestock is recognized as being so important to Africa that the Food and Agriculture Organization (FAO) of the United Nations (FAO 2023b) states that the future of African livestock

will influence the development of the entire continent. Despite the recognition of its potential, livestock resources in Africa are underdeveloped and not in a position to contribute toward meeting the nutrition and economic needs of Africans nor to counter the challenges posed by changing climatic conditions, emerging market demands, and unpredictable upheavals.

The FAO estimates the total African human population at 1.39 billion in 2021, with rural and urban populations of 777 million and 609 million, respectively (FAOSTATS 2022) (Fig. 1.1), and it is projected to reach 2.5 billion by 2050 (UN 2022). A steady annual increase of both the urban and rural populations by 3.7% and 1.8%, respectively, since 2010 is accompanied by an increased demand for animal products. In particular, the livestock sector supports the livelihood of about 65% of Africa's population, especially those living in rural areas. The FAO indicates that the number of undernourished people in Africa rose from 178 million in 2005 to 282 million in 2022, which is 38% of the total number of undernourished people in the world in 2022 (FAO 2023c). The rising number of chronically undernourished people in Africa may pose a challenge to achieving the UN-SDGs of eradicating hunger in Africa by 2050. Livestock is thus critical for Africa, and indigenous AnGR can be the basis of developing a resilient, sustainable, and productive livestock sector, but investments to date have been inadequate, and hence, the livestock sector is underdeveloped, and the potential of indigenous AnGR remains unexploited.

A joint study by the FAO, International Livestock Research Institute (ILRI), and African Union-InterAfrican Bureau of Animal Resources (AU-IBAR) estimated that the meat and milk markets will reach 34.8 and 82.6 million tons by 2050, corresponding to increases of 145% and 155%, respectively, compared to year 2005/2007 (Pica-Ciamarra et al. 2023). As a result, consumer demand will surpass production if concerted actions to increase livestock productivity are not taken. Africa may, therefore, continue to be a prolific importer of livestock products if current national, regional, and continental livestock development strategies are not implemented. The rapid transformation and sustainable development of Africa's livestock sector will require the cooperation of all stakeholders; investments in the development of personnel and the use of innovative technologies such as improved feeding, housing, healthcare, marketing, improved

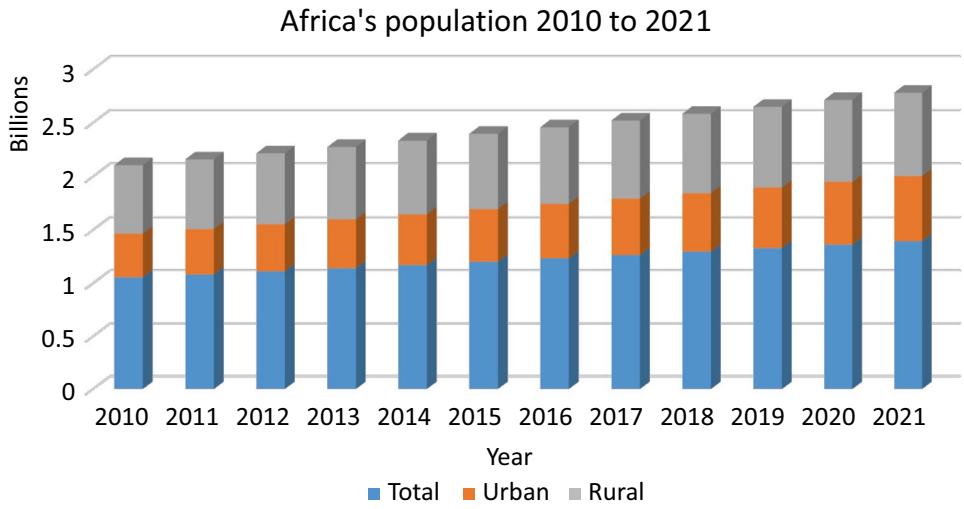

Fig. 1.1 Africa's total, rural, and urban population statistics for the years from 2010 to 2021

animal genetics, and biosecurity; and an evolution of a more business-focused livestock sector. These laudable objectives will, however, require an understanding of every aspect of the livestock genetic resources and production systems for informed targeted interventions. This book chronicles the current facts about the main African livestock genetic resources, specifically cattle, goat, sheep, poultry, pig, dromedary, donkey, horse, buffalo, and nonconventional animal resources (rabbit, snail, frog, and honey bee), addressing five major themes summarized in sections 1.2, 1.3, 1.4, 1.5, and 1.6.

1.2 African Livestock Genetic Resources and Production Systems

The domestication of the present-day African livestock genetic resources has been shaped by a delicate balance between human activities, natural selection, and environmental adaptation (Ibeagha-Awemu et al. 2019) under diverse production systems (Chap. 2). African livestock production systems are heavily dependent on seasonality and the amount of rainfall, which, in part, determines the species of livestock raised in different agroecological zones. According to the population size (number of individuals), chicken (59.37% of the main livestock genetic resources) is the most predominant livestock species in Africa, followed by goat (13.49%), sheep (11.69%), and cattle (10.46%) (FAOSTATS 2022). Chapter 2 details the characteristics, unique features, status, trends, and driving factors of African livestock production systems, which are generally classified as small-scale (pastoral, agropastoral, mixed small holder farming, free range, and urban/peri-urban), medium-scale, and large-scale (pastoral, ranching, commercial intensive and extensive farming, cooperative farming, and state-owned farms). Special emphasis is given to pastoral systems, which play a big role in African livestock production as well as the social, economic, and biophysical aspects of production systems with implications for improvement. Chapter 2 concludes with a discussion of the main challenges limiting livestock production, the possible interventions for livestock development in Africa, and a presentation of the drivers and enabling factors that could shape the future transformation of African livestock production systems to respond to the increasing demand and other trends, which will affect the contexts of both supply and demand of livestock and livestock products.

Knowledge on the historical origins and production characteristics of the main livestock genetic resources in Africa, the breeds, and

unique features of taurine cattle (Chap. 3), zebu, zebu-taurine derivatives and established exotic breeds (Chap. 4), goat (Chap. 5), sheep (Chap. 6), poultry (chicken, guinea fowl, and duck) (Chap. 7), pig (Chap. 8), dromedary (Chap. 9), donkey (Chap. 10), horse (Chap. 11), and buffalo (Chap. 12) is essential for their development. These chapters (3–12) chronicle the origins, available knowledge on the breeds/breed types, breed names as used in different countries/regions, physical and production characteristics, special characteristics, and distribution in the African continent and genetic diversity, which together contribute to the reliable prediction of genetic performance of the genetic resources in defined environments so as to provide a basis for their development, taking advantage of their unique attributes. Current uses and geographical distribution (including indicative ecological parameters that define these systems) are also covered. These chapters allude to the role that traditional breeding and indigenous knowledge of livestock keeping and maintenance have played in shaping the diversity in these genetic resources over millennia. Lesser known or underutilized nonconventional animal genetic resources (the Goliath frog, snail, rabbit, and honeybee), which also contribute significantly as food sources and income generators in the continent, are covered in Chap. 13.

Agricultural activities including livestock farming contribute to greenhouse gas (GHG) emissions, with livestock contribution to emissions estimated at about 15% of global methane emissions and 65% of global nitrous oxide emissions, which amount to an estimated 8–11% of global anthropogenic GHG emissions (IPCC 2007). Chapter 14 presents available information on the contributions of African livestock to GHG emissions and global warming in the face of changing climatic conditions. The chapter also examines actions needed to mitigate the impact of animal agriculture on climate change and the role indigenous African genetic resources can increasingly play in enhancing climate adaptation in livestock systems.

1.3 Opportunities for the Improved Utilization of African Livestock Genetic Resources

In comparison to breeds that have been under sustained intentional breeding and selection programs for many decades, African livestock are generally considered underproductive. Such generalizations are not accurate for at least two reasons. First, the majority of African livestock have been subjected neither to sustained selective breeding nor to improved management. Second, productivity measures used have tended to ignore adaptive attributes, which enable indigenous African livestock breeds to survive and produce in extremely challenging environments with near-zero external inputs. Only very few African countries have functional livestock breeding programs that focus on long-term improvement of indigenous breeds. Any livestock breed improvement program starts with defining the breeding goal (Goddard 1998), which will determine the traits to be improved, the direction and rate of genetic change, and the appropriate genetic evaluation system to be implemented. Chapter 15 defines breeding goals and expends the concepts of breeding strategies for improving livestock under various African livestock production systems. It also examines the economic value of breeding goals, the systems for adequate routine data capture, and the opportunities increasingly becoming available to use digital mobile tools for routine data capture. The chapter also presents sample breeding strategies for small ruminants and cattle and highlights the integration of essential elements of breeding strategies in the African context.

Chapters 16 (cattle and buffalo), 17 (goat and sheep), 18 (poultry), and 19 (pig) define breeding goals and breeding strategies for sustainable livestock improvement in African low- to high-input production systems. These chapters cover critical traits and discuss the importance of directional breed formation that responds to demand patterns, the importance of maintaining pure breeds

for future use, strategies for gainful exploitation of crossbreeding to improve traits of economic importance, the importance of the male in breed improvement, aspects of adaptation and resilience in African agroecological zones, and the lessons learned and best practices. These chapters also examine past breed improvement efforts and sample results in different countries/regions, lessons learned, and the prospects for future advances.

1.4 Leveraging Modern Technologies for the Improved Utilization of African Livestock Genetic Resources

Technological advances have been instrumental in driving different dimensions of development, and present-day advanced technologies are facilitating breakthrough innovations in medicine and agriculture, including livestock production. It is expected that developments in genomics, phenomics, nutrition, reproduction, health and management technologies will support rapid progress in livestock development, including in developing more productive and resilient animals suitable for the diverse production environments of the continent.

Chapters 20 and 21 chronicle the various technological innovations that have resulted in advances in breeding, nutrition, health, and reproduction in livestock across the globe and the opportunities they present for Africa. Key issues related to the adoption of modern technologies as well as the challenges and opportunities for the application of modern technologies for sustainable livestock production in African livestock production systems are discussed. Using practical examples, the chapters demonstrate that the modern technologies necessary to advance African livestock productivity are available but that these have not been fully harnessed by the continent.

Prospects for the utilization of modern technologies by species are presented in Chaps. 22 (cattle), 23 (poultry), and 24 (goat, sheep, and pig). These chapters focus on specific technologies that have been applied in each species/group and present case studies on their application in Africa's low-, medium-, and high-input livestock systems. The conclusion here is that the technologies with potential are available and can support rapid genetic progress in African livestock. Taken together, the analyses presented in these chapters emphasize that it is imperative that African nations invest in human and institutional capacity to effectively utilize the available and emerging modern technologies in livestock research and development.

1.5 Conservation of African Livestock Genetic Resources

As alluded to above, Africa is home to a high diversity of some of the world's livestock genetic resources (AnGR). Importantly, although the indigenous African livestock genetic resources present unique opportunities for improving production and productivity in the diverse African environments, they are threatened as major genetic erosion continues to happen even before they are adequately characterized. Thus, deliberate interventions are needed to improve the management of AnGR in all situations, including where the AnGR are most at risk (Seré et al. 2008). Conserving Africa's AnGR is an essential initial step toward maintaining AnGR for current and future production objectives and environmental challenges.

Chapter 25 discusses the need, options, and tools for the conservation and management of AnGR. The operational procedures/guidelines of past and current conservation efforts in Africa are also discussed, as well as the opportunities of exploring genomics and other modern technologies in conservation programs. The challenges of applying in situ and ex situ conversation and current conservation efforts are addressed. Issues around policies and regulations governing the conservation and improved management of AnGR and the future opportunities for conserving African livestock genetic resources are also discussed.

Chapter 26 examines the economic considerations, the framework of conservation of livestock genetic resources, and the institutional frameworks for the exchange and utilization of AnGR. The methods and tools for the economic valuation of AnGR and for estimating the economic and social benefits and costs of AnGR conservation are presented. Components of the economic framework for the sustainable use and conservation of AnGR in terms of creating awareness, capacity development, data availability, and access to data, resources, and incentives for the conservation of AnGR are also presented.

1.6 Institutional Arrangements and Enablers for the Enhanced Utilization of African Livestock Genetic Resources

Enhanced utilization of African livestock genetic resources will require the acquisition and mastering of a diverse set of skills and knowledge going well beyond livestock breeding and management. Animal genetic improvement is generally regarded as the science of increasing the genetic merit of a future population through the intentional selection and mating of genetically superior parents. The technical know-how to achieve this requires multilevel education and training that integrates knowledge from multiple disciplines such as quantitative genetics, population genetics, genomics, statistics, molecular biology, biochemistry, computer science, and geography, among others. Chapter 27 presents the current status of animal genetic improvement education in Africa, evaluates graduate education in Animal Breeding and the associated institutions, identifies the gaps in the current curricula, and makes recommendations to strengthen the existing training. Suggested strategies for capacity strengthening include curriculum overhaul for tertiary education, retooling of trainers and researchers, tailored training for farmers, and the facilitation of access to research resources such as sharing arrangements for the use of facilities at national, regional, and international research institutions (e.g., the Biosciences eastern and central Africa (BecA) and shared laboratories at the ILRI campus in Nairobi, Kenya).

Increased livestock productivity with the potential to enhance the livelihoods of rural dwellers is central for the achievement of UN-SDGs (FAO 2015) for Africa. Specifically, the contributions of livestock breeding and genetic improvement and Africa's livestock development strategy aimed at making available animal-sourced foods for the achievement of UN-SDGs for Africa are presented in Chap. 28. Key capacity building areas in livestock breeding and genetic improvement for achieving UN-SDGs for Africa include the improvement and maintenance of livestock genetic diversity, livestock conservation, market-driven capacity development in modern livestock breeding strategies, sustainable intensification of livestock production practices, adaptation of livestock farming practices to changing environmental conditions, tailored breeding for enhanced animal welfare, adaptability and biosafety, smart farming and breeding strategies with the implementation of big data and artificial intelligence, and infrastructural development and tailored policies for technology uptake for sustainable and enhanced livestock development. The analyses of these needs are covered in Chap. 28.

Multicounty cooperation or initiatives (MCIs) are considered powerful approaches to enhance the efficiency and effectiveness of livestock breeding programs. The subcommittee of the international committee for animal recording known as INTERBULL (https://interbull.org/) has effectively deployed multicountry evaluations for dairy bulls across Europe for decades. Chapter 29 examines what would be required, including data recording and analysis methodologies and tools, for African countries to establish robust systems for the genetic evaluation of livestock across multiple countries. In addition to the opportunity to effectively use limited human and physical resources (including data storage and computing equipment) across countries, key benefits of such an approach will be the quantification of how different genotypes interact with the diverse environments and the evaluation of per-

formance under different environmental and management conditions.

Chapter 30 presents an analysis of the policy and legislative environment, including an examination of the status of relevant policy and legislation instruments in African countries, and the engagement of Africa in the development and implementation of global policy instruments and frameworks to ensure that these are relevant for the diverse contexts of Africa. The latter includes coverage of both Nagoya and Cartegena Protocols, which address ownership, sovereignty, access, and benefit sharing of genetic resources. Overall, the chapter attempts to examine the extent to which African countries are paying attention to relevant policies locally and engaging effectively in subregional, continental, and international discourses that are shaping the global policy landscape that has implications for AnGR.

Finally, sustainable livestock production is among the prerequisites for meeting the food needs of Africans and the economic development of the continent, and achieving this *involves the participation and cooperation of many stakeholders*. Chapter 31 concludes this book by presenting the roles of various institutions—public, private, civil society, and farmer organizations—within and between countries, as well as linkages to international players, including research institutions in the North and development partners, which support livestock research and development. The chapter examines the challenges associated with building functional partnerships and concludes by emphasizing the key pillars that underpin effective development interventions: enabling policies, functioning institutional arrangements, access to appropriate technologies, funding and information, and adequate infrastructure and trained personnel.

1.7 Conclusion

This introductory chapter is an overview of the material covered in this book. It is intended to point the reader to materials of interest in the book.

2 African Livestock Production Systems: The Past, Present and the Projected Future

Eveline M. Ibeagha-Awemu,
Richard Osei-Amponsah, and Martha N. Bemji

Abstract

Africa is home to diverse livestock genetic resources (AnGR), which have contributed and continue to contribute to the livelihoods of Africans and the economic development of the continent (Section 2.1). Livestock farming engages about 65% of Africans, predominantly rural dwellers, and its evolution is shaped by many factors such as agro-ecological conditions, socio-economic variables, land availability, species, goal of production and technological and institutional factors, among others. Consequently, a wide variety of livestock production systems are practised in Africa, even within the same agro-ecological zones or regions. Depending on the agro-ecological zone and the level of investment/technical know-how, the main livestock production systems range from small-scale subsistence to large-scale extensive and intensive systems (Section 2.3). Generally, African livestock production is dependent on rainfall, and while about three-quarters of Africa's agricultural land is classified as grassland, over 70% of livestock productivity takes place in the small-scale production systems characterised by low farm size (animal numbers), limited access to adequate nutrition and healthcare and generally low inputs and outputs (Section 2.4). With the rising human population and demand for livestock products, the current level of livestock productivity is not meeting consumer demand, a situation that will worsen in future years. As a remedy, current livestock production systems must be understood as a first step to putting in place more productive systems. This chapter presents the characteristics of present-day African livestock production systems, their challenges, and factors that could shape future more productive livestock production systems.

2.1 Introduction

Livestock refers to various domesticated animal genetic resources (AnGR) that are of food, cultural and economic value to those who keep them. In Africa, typical animal species that constitute animal agriculture include ruminants (cattle, sheep, goat and buffalo), pseudo-ruminants (camel, rabbit and horse), donkey, pig and various poultry species (chicken, guinea fowl, turkey and duck). Livestock are raised in Africa to provide a broad array of goods and services such as (1) food (meat, milk and eggs), (2) energy for land tilling and transport, (3) manure for fertilising fields, (4) raw materials (hide, skin and hair), (5) employment for smallholder farm families and professionals, (6) social roles (dowry payment, sport and competition, burial and other traditional ceremonies), (7) religious roles (use in religious festivals like Christmas, Ramadan, etc.), (8) status and social symbol, (9) a form of insurance (livestock sold for cash when needed), (10) risk reduction through provision of diversified production, (11) environmental sustainability through nutrient recycling and landscape and biodiversity maintenance and (12) contribution to the circular economy. In addition to livestock playing a central role in the livelihoods of African communities, they contribute significantly to the agricultural gross domestic product of many African countries (10–50%) (AU-IBAR 2019). Livestock is intricately interwoven with the livelihood of farming communities on the continent to the extent that most indigenous breeds are named after tribes or specific production regions. Therefore, it is vital to understand the systems in which the livestock are produced in the face of rapid human population growth and how existing livestock production systems can be sustainably maintained and improved to meet future production goals.

The scale, goal, nature and management of a farming initiative is referred to as a production system. Agricultural production systems are the ways in which farmers make use of available resources to their food and agriculture needs. According to the Food and Agricultural Organization (FAO) (FAO 2020a), livestock production systems encompass all aspects of the use and supply of livestock and livestock products, including their number and distribution, the various production systems, estimates of present and future consumption and production, the people directly implicated in producing livestock, the associated benefits and their economic and environmental impacts. Thus, the ecological system, husbandry and management practices, and levels of input collectively define a livestock production system, and various combinations of these factors depict a rich variety of livestock production systems in Africa, often broadly classified as extensive, semi-intensive and intensive. These systems vary from region to region depending on the resource availability and/or allocation, production objectives, scale of operation, target market and the cultural values of the local communities. The unique features of livestock

production systems in Africa include their integration into crop farming, extensive pastoral nature, free range, multiple objectives, heterogeneity of labour, keeping of multiple breeds and crossbreds, and irregularity of feed, veterinary services and markets. The subsistence or smallholder livestock production system predominates and often targets the needs of farm families with no immediate objective of making a profit from the sale of animals and animal products.

A main characteristic of these major systems is their low productivity, which falls short of meeting increasing consumer demands for animal products by an increasing human (Africa) population currently estimated at 1.39 billion and projected to reach 2.5 billion by 2050 (FAOSTATS 2022; UN 2022). To meet the shortfalls in livestock productivity, African governments have resorted to the importation of animal products, a trend that goes up yearly (Ibeagha-Awemu et al. 2019; FAOSTATS 2022). Fuelled by the increasing demand for livestock products driven by urbanisation, increasing standards of living and changing lifestyles, animal production in Africa is slowly evolving from a predominantly traditional subsistence farming relying on large numbers of animals towards intensification and production efficiency. Several factors are critical components of this evolution including the availability of innovative technologies, improved animal genetics, improved management strategies (feeding, housing, healthcare, marketing and biosecurity) and the emergence of more business-focused livestock farmers. As a result, various forms of semi-intensive-to-intensive livestock production systems are emerging across the African landscape.

This chapter presents the main features, status, trends and driving factors of African livestock production systems and the distribution and population trends of commonly farmed animal genetic resources (cattle, sheep, goat, buffalo, camel, donkey, rabbit, horse, pig, chicken, guinea fowl, turkey and duck) and various non-conventional animal genetic resources. The chapter also presents the factors limiting livestock production and possible mitigations, as well as possible enablers that could shape future livestock production systems and directions for more sustainable and environmentally friendly production practices.

2.2 Overview of African Livestock Genetic Resources and Agro-ecological Zones

The livestock genetic resources exploited for food and economic gains on the African continent as well as the agro-ecological zones shaping various livestock production systems will be presented in this section. More detailed descriptions of these AnGRs are found in Chapters 3, 4, 5, 6, 7, 8, 9,10, 11, 12, and 13.

2.2.1 African Regional Livestock Genetic Resources

The five major regions of the African continent (East, Central, North, South and West) support diverse species of livestock, their introduction or domestication being shaped by a delicate balance between human and natural selection and environmental adaptation (Ibeagha-Awemu et al. 2019). Based on the FAO statistics (FAOSTATS 2022), the populations of the main livestock species in Africa and their rate of annual increases in the past 11 years are shown in Table 2.1 and Fig. 2.1a, b. According to numbers from the year 2021, chicken is the most predominant livestock, constituting about 59.37% of Africa's main livestock genetic resources, followed by goat (13.49%), sheep (11.69%) and cattle (10.46%). Cattle and small ruminants (goat and sheep) are the predominant ruminant species in East and West Africa, accounting for about 67.27% of the continent's ruminant (cattle, sheep, goat and buffalo) livestock. Among the major livestock species, North Africa is the lead producer of chicken (33.91%), followed by West Africa (32.74%); East Africa is the lead producer of cattle (48.05%), followed by West Africa (22.71%); West Africa is the lead producer of sheep (31.14%), followed by North Africa (26.55%); West Africa is the lead producer of goat (37.68%), followed by East Africa (36.84%); and East

Table 2.1 Livestock populations[a] in Africa and regions in the year 2021

	Africa (total)	Annual increase[b] (%)	East Africa	Central Africa	North Africa	Southern Africa	West Africa
Cattle	373,198,697	2.07	179,333,640	51,340,196	40,590,648	17,177,334	84,756,879

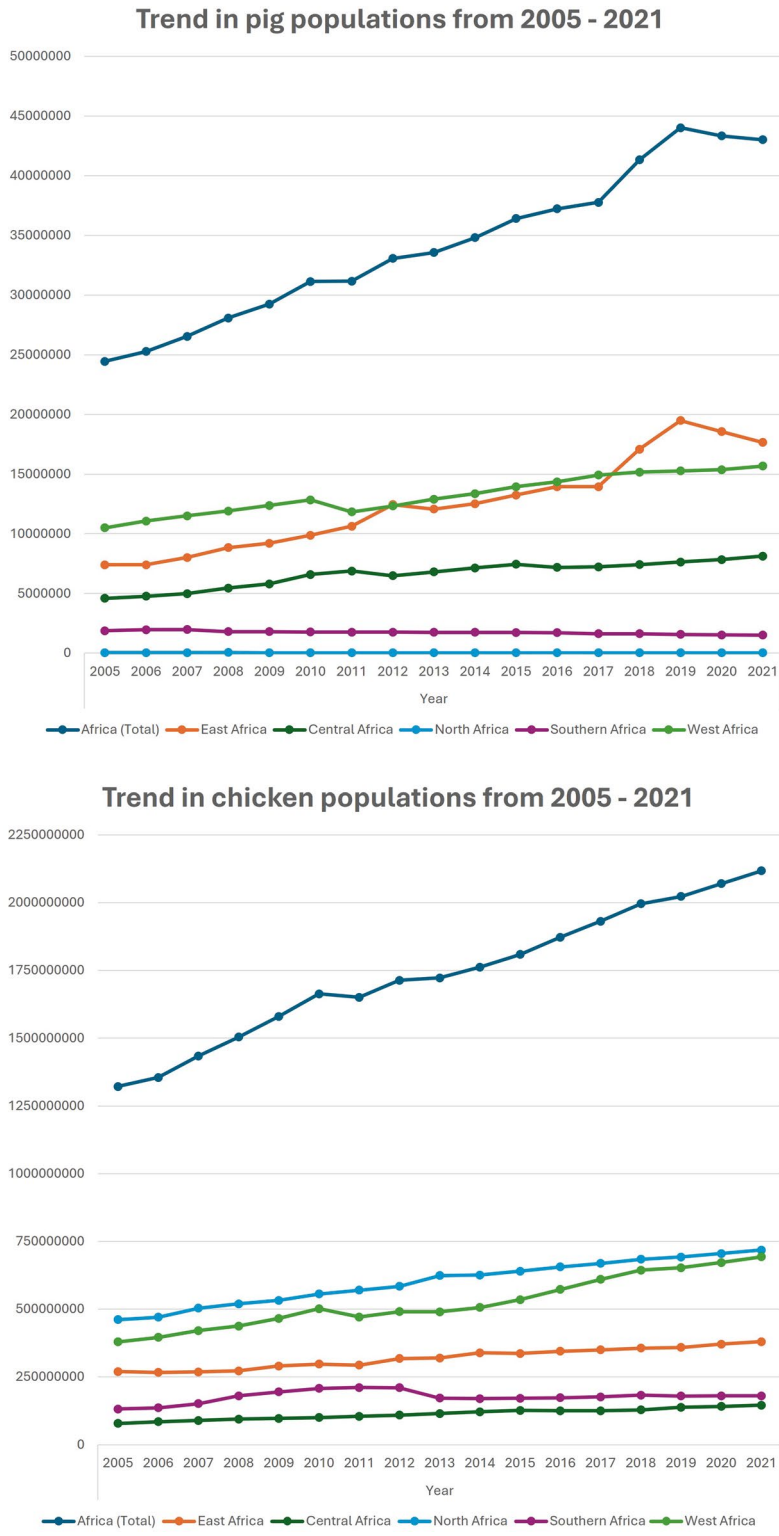

Fig. 2.1 (continued)

Africa is the lead producer of pig (41.04%) followed by West Africa (36.45%). Among the less common domesticated livestock species, North Africa is the topmost producer of buffalo (over 95%), turkey (90%) and rabbit and hare (46.26%). More details on the characteristics and genetic diversity of the major African livestock genetic resources and non-conventional animal genetic resources are presented in Chapters 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, and 13.

African livestock farming is heavily dependent on rainfall, and the livestock populations or their native habitats are shaped by the prevailing agro-ecological zones. Most of the present-day livestock production in Africa is characterised by low inputs and outputs and not being able to meet the increasing demand for livestock products. Due to low livestock productivity, African governments increased beef imports from 482,111 tonnes in 2012 to 612,353 tonnes in 2016 and pork imports from 184,322 tonnes in 2012 to 252,611 tonnes in 2016 (Ibeagha-Awemu et al. 2019). To position the livestock sector to positively contribute to animal protein food supply and the socio-economic development of the continent, it is imperative to ensure sustainability in African livestock production systems since livestock directly contribute to the achievement of all 17 United Nation's Sustainable Development Goals (SDGs) and the goals of the Livestock Development Strategy for Africa (LiDESA) 2015–2035 (AU-IBAR 2015; UN 2015). Since the livestock sector has the potential to enhance the livelihoods of Africa's subsistence farmers, understanding today's livestock production systems will pave a way to putting in place more productive systems.

2.2.2 Agro-ecological Zones of Africa and Livestock Production

Geographical areas displaying similar climatic conditions (e.g. rainfall, temperature, humidity, wind speed, etc.) and vegetation that govern their ability to support rain-fed agriculture including livestock farming are known as agro-ecological zones. Agro-ecological zones in Africa are delineated by various factors including latitude, elevation, highland/lowland (warm or cool based on elevation), temperature, moisture zones (water availability), rainfall (including rainfall amounts), seasonality, duration of rainy season, length of growing season and the species/amount of vegetation, which also influence the livestock species kept by farmers. Based on these factors and considering the major climatic zones of Africa (tropics and sub-tropics), four major agro-ecological zones can be distinguished in Africa: arid, semi-arid, sub-humid and humid (Fig. 2.2a). Within these major agro-ecological zones are found sub-tropical warm and cool regions as well as tropical warm and cool regions. The main characteristics of African agro-ecological zones are summarised in Table 2.2. The main livestock production systems of the agro-ecological zones determined using factors such as land cover, days of growing period, highland and temperate areas, human population and irrigated areas (Robinson et al. 2011) are depicted in Fig. 2.2b. Notable arid zones of Africa are the Sahara desert in Northern Africa and the Namibian and Kalahari deserts in Southern Africa. As shown in Fig. 2.2b, large areas of sub-Saharan Africa (SSA) are dominated by mixed crop–livestock systems. Moreover, of the four major agro-ecological zones (arid, semi-arid, sub-humid and humid) in SSA (Dixon et al. 2001), arid and semi-arid agro-ecological zones cover 43% of the land area. In West Africa, 70% of the total population lives in the moist sub-humid and humid zones, whereas in East and Southern Africa, only about half the population occupies these areas. According to Otte and Chilonda (2003), production parameters of ruminants in the traditional systems of SSA published in the literature between 1973 and 2000 are generally poor, without marked differences between systems, agro-ecological zones, or sub-regions. Spatial analysis by the authors revealed regional variations in the availability of meat and milk per person, showing that per capita beef and milk supply were highest in the regions with smallholder dairy systems and lowest in the humid zones of Central and West Africa. Three-quarters of agricultural land can be classified as grassland

Southern Africa	Days of growing period/year	<60	60–120	120–250	270–330
	Mean annual rainfall (range)	Up to 269.2 mm	Up to 464 mm	650–982 mm	880–1550 mm
	Mean annual temperature	24–31 °C	22–29 °C	20–28 °C	18–25 °C
	Main livestock species	Cattle, goat, sheep, pig and poultry	Dorper sheep, Damara sheep, Boer goat, pig, donkey and poultry	Cattle, goat, sheep and equines	Chicken, cattle, pig, goat, sheep, deer, duck and turkey
	Main plant/tree species	Maize, millet, sorghum, barley, cassava, groundnut, cowpea, cabbage, carrots and date palm	Maize, millet, sorghum, barley, cassava, groundnut, cotton, cowpea, butternut, melon and watermelon	Sweet potato, cotton, cassava and cowpea	Maize, cassava, banana and orange

[a]The data in this table were compiled from the following sources: https://gaez-data-portal-hqfao.hub.arcgis.com/, Fischer et al. (2002), Muimba-Kankolongo (2018) and Vrieling et al. (2013)

across Africa (Otte et al. 2019), with over 70% of livestock production taking place in small-scale production systems characterised by low animal population numbers and generally low inputs and outputs (Ibeagha-Awemu et al. 2019).

2.3 African Livestock Production Systems

In its broadest sense, livestock production systems, which are subsets within the agriculture sector, describe the type of animal genetic resources raised in specific environments using specific management practices and for specific purposes by producers. The path and rate at which livestock production systems evolve depend on many factors such as the interaction of the crop with the livestock, agro-ecological conditions, socio-economic variables (such as days of growing period and distance to markets to acquire inputs and sell produce), technological and institutional factors, land availability, goal of production, intensity of production and product type, as summarised in Fig. 2.3. The level of investments or inputs in terms of feeding, healthcare, housing, innovative technologies and marketing varies between production systems. Consequently, a wide variation in livestock production systems is found in Africa, even within the same agro-ecological zones or regions. Based on climate change, the FAO (2009) classified African livestock production systems into grazing systems, mixed farming systems and industrial systems. Grazing systems were further subdivided into extensive and intensive, while mixed farming systems were broken down into irrigated and rain-fed. Industrial systems include highly intensive cattle, pig and poultry production systems. Large areas of the Horn of Africa, Southern Africa and the Sahel are dominated by grazing systems, and grazing and mixed systems feature in West Africa and some parts of East Africa, with smaller areas in Southern Africa (Simpkin et al. 2020). Recently, the African Union-InterAfrican Bureau for Animal Resources (AU-IBAR) (AU-IBAR 2019) broadly classified African livestock production systems into three main categories, namely (1) agro-pastoral and pastoral systems, (2) mixed crop–livestock systems

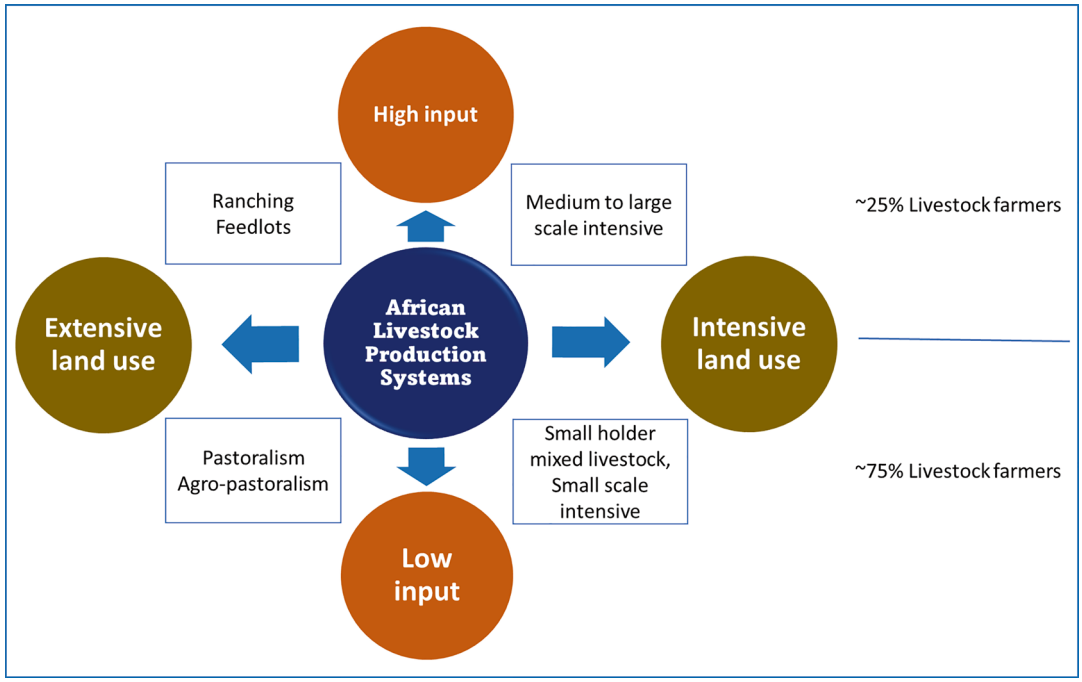

Fig. 2.3 Progression of African main livestock production systems according to land availability and level of inputs

and (3) landless systems. For instance, most ruminants (cattle, sheep and goat) in Africa are reared in production systems that vary from very-low-input, large-scale, extensive pastoral production systems to high-input, small-scale, intensive production systems.

Depending on the agro-ecological zone, different forms of these systems from small-scale (pastoral, agro-pastoral, mixed smallholder farming, free-range and urban/peri-urban) to large-scale (pastoral, ranching, large scale commercial intensive and extensive farming, cooperative farming and state-owned farms) are practised and have various levels of inputs. Subsequent discussion on the various livestock production systems will focus on these major categories.

The main characteristics of African livestock production systems are summarised in Table 2.3.

2.3.1 Small-Scale Livestock Production Systems

These are extensive low-input livestock production systems, which may be broadly categorised as small-to-medium-scale extensive pastoral/agro-pastoral and transhumance systems, mixed smallholder, free-range and urban/peri-urban livestock production systems characterised by low inputs and limited number of animals.

2.3.1.1 Pastoral and Agro-pastoral Systems

Pastoralism, coined from the word pastor, or herder, generally signifies herdsmen, livestock in motion and rangelands. Thus, pastoralism is generally regarded as a finely interwoven interdependent relationship between livestock, local environment or ecology and pastoralists in resource-limited, marginal (climate) and highly variable environmental (temperature, rainfall, pasture, etc.) conditions (Fig. 2.4). Pastoralism represents a multifaceted form of natural resource management that involves the interaction between the natural resource system, the resource users system and the geopolitical system in place (Pratt et al. 1997). The pastoralism livestock system is practised in different forms and scales (Box 2.1), which could be at a small scale (up to 100 heads) or a large scale (more than 100 heads).

Table 2.3 Key features of African livestock production systems[a]

Major category	Production system	Primary livestock types	Source of labour	Characteristics	Input	Output	Utilisation of output	Constraints
Small scale	Pastoral (sedentary)	Cattle, sheep, goat, camel, donkey	Family unit	Few to hundred animals, high mortality	Open communal grazing land shared depending on the herd size, manure	Low production of meat, milk, hide and skin, draft power	Primarily for own consumption and sale	Recurrent drought, conflict, weak governance, disease, lack of veterinary services and feed resources, loss of grazing lands, loss of labour to urban migration
	Transhumance pastoralism	Cattle, sheep, goat, camel, donkey	Family unit	Few to hundred animals, high mortality	Move animals to different pasture lands according to the season	Low production of meat, milk, hide and skin	Primarily for own consumption and sale	Recurrent drought, conflict, weak governance, disease, lack of veterinary services and feed resources, loss of labour to urban migration
	Nomadic pastoralism	Cattle, sheep, goat, camel, donkey	Community	Large community herds	People and livestock settle where pasture is found and migrate to new pastures when necessary	Low production of meat, milk, hide and skin	Primarily for own consumption and sale	Recurrent drought, conflict, weak governance, disease, lack of veterinary services and feed resources

(continued)

Table 2.3 (continued)

Major category	Production system	Primary livestock types	Source of labour	Characteristics	Input	Output	Utilisation of output	Constraints
	Agro-pastoral	Cattle, sheep, goat, camel, poultry	Family members	Settled with few to hundreds of animals but migrate for survival, involved in crop cultivation	Open communal grazing land, crop by-products, manure, labour and seeds	Low production of meat, milk, hide and skin, draft power, crops	Mainly for home consumption, with a small portion sold or battered	Disease, drought, migration of labour to urban areas for jobs, conflict, weak governance, lack of veterinary services and feed resources
	Mixed smallholder farming	Sheep, goat, pig, poultry, cattle	Ranges from family unit to hired labour, depending on the herd size	Small herd size, proximity to markets in urban cities, specialisation in crop and animal farming	Crop by-products, household wastes and forage, limited access to inputs such as commercial feeds, manure, fertiliser, improved seeds and irrigation	Low production of meat, milk, hide and skin, draft power and crops	Home consumption and sale	Disease, drought, loss of labour to urban migration, conflict, weak governance, limited access to veterinary services and feed resources
	Urban/peri-urban	Sheep, goat, pig, poultry, rabbit, cattle	Mainly family unit and hired labour	Small herd size, housed in backyard enclosures	Crop by-products, household waste, commercial feed and pasture	Low production of meat, milk and eggs	Mainly for sale with a limited quantity retained for home consumption and sale	Disease, high cost of drugs and feed and limited water resources and housing

Large scale	Pastoral	Cattle	Family unit and hired labour	Large herds of animals (>100), high mobility	Open communal grazing land	High animal numbers, low production of meat, milk, hide and skin	For commercial purpose	Drought, diseases, limited access to veterinary services and land, conflict
	Ranching	Cattle, sheep, goat	Mainly hired herders, depending on the herd size and supported by family members in some instances	Large herd size, high input through fencing, pasture management, rotational grazing, health management, infrastructure	Large rangeland, veterinary services, drugs, vaccines, supplemental feeding, especially during the dry season	Meat, milk and hide	For commercial purpose	Diseases, limited access to veterinary services and land
	Large-scale intensive commercial farming	Cattle, poultry, pig	Hired labour	Access to amenities, infrastructure, organised structure, access to local and export markets	Veterinary services, drugs, vaccines, feed mill, modern equipment	Meat, milk, hide and eggs	For commercial purpose	Diseases and instability in government policies
	Cooperative farming (community breeding)	Cattle, sheep, goat, poultry	Farm families and also hired labour	Limited access to amenities, infrastructure, local and export markets Weak organisational structure	Veterinary services, drugs, vaccines, feeds, few equipment	Meat, milk, hide and eggs	For commercial purposes	Diseases, unstable government policies
	State-owned farms	Cattle, sheep, goat, poultry	Civil servants employed by the state	Financed by government, access to local and export markets	Veterinarians and other livestock professionals, modern equipment and access to government facilities	Meat, milk, hide and poultry	For commercial purpose	Diseases, unstable government policies and bureaucracy

[a]Modified from Ibeagha-Awemu et al. (2019)

Fig. 2.4 Pastoralism in West Africa, specifically in the Bamenda Grasslands of Cameroon (**a**) and the Sahel region of Burkina Faso (**b**). (Photos by Dr. Eveline M. Ibeagha-Awemu)

In Africa, pastoralism is an activity practised by over 22 million people, who belong to a few ethnic groups such as the Bedouins, Berbers, Boran, Fulani, Maasai, Mbororo, Somali and Turkana tribes. Several forms of pastoralism livestock systems are found in Africa (Box 2.1).

The pastoral/agro-pastoral system spans about 20 countries and extends over 4.8 M km^2 of land, including 0.68 M km^2 of cropland, in semi-arid regions of North Africa, the Sudano-Sahelian belt stretching across West and Central Africa and East and Southern Africa (Nidumolu et al. 2022). These areas are home to about 99 million people (in 2015) with a mean livestock holding of four tropical livestock units (TLU) and mean harvested area of 3.8 ha per farm (Dixon et al. 2019). Large-scale extensive pastoral and transhumance systems are found mainly in arid and semi-arid areas of the continent where the potential for crop farming is low. Based on the degree of aridity, variations could exist in terms of the amount of rainfall, growing period, type of pastoralism, migration pattern and the types of species reared.

Box 2.1 Forms of pastoralism

Pastoralism: This is the practice of grazing livestock in natural open pastures with little or no further inputs. The main livestock are cattle, sheep and goat.

Transhumance: This is a form of pastoral livestock management system involving the herding of animals to different geographical grazing locations (could be near or distant) over a period, typically determined by seasonal variations.

Nomadic pastoralism: Nomads are communities of people with no fixed settlement, and those who practise pastoralism are referred to as nomadic pastoralists. Nomadic pastoralism is the movement of a community and their livestock from place to place in search of pasture. Animals and nomads will settle where grazing has been found until the location is no longer sustainable, prompting migration.

Agro-pastoralism: Farmers grow crops in addition to keeping livestock under a pastoral system of management.

Silvo-pastoralism: It is a system that integrates livestock (pastoralism), trees and forage production at the same location.

Arid pastoralism: This is the practice of pastoralism around scattered oases in sparsely settled arid areas of Africa. The main livestock are cattle, sheep, goat and camel, and the main crops are date palm, irrigated crops and vegetables.

Characteristics Pastoral livestock system of management is based on grazing natural vegetation, which is often of low nutritional quality, and the availability/distribution depends on the variability and intensity of annual precipitation. Pastoral management is characterised by the adaptation of the feed requirements of the animals to the environment through constant movement in search of grazing or migration. Access to feed resources (grazing areas, crop residues, etc.) and water for livestock in pastoral systems is of critical importance in the arid and semi-arid regions of Africa due to highly variable rainfall amounts, frequency and duration (see Table 2.2). Pastoralists are flexible in the manner of their operations, which gives rise to multiple systems including nomadic, transhumance, agro and arid systems. The nomadic system is very flexible, involving regular seasonal migration of livestock in search of pasture. Nomads do not have a base or home, and wherever pasture is available for their animals is considered home until the pasture is no longer sustainable or available. Generally, there is little variation in daily grazing movements of herds around the base locations (camps, villages and water points) with most radii of dispersion below 6 km but wide variation in the seasonal movements between base locations (Turner and Schlecht 2019). The magnitude of mobility parameters is the highest for transhumance systems moving along latitudinal and elevation gradients. Transhumance, on the other hand, is the regular movement of livestock to specific locations to exploit the seasonal availability of pastures and water. In West Africa for example, animals are moved from the more arid northern areas during the dry season to the humid and subhumid southern regions in search of pasture and water. Transhumance is beginning to evolve in response to changing cultural and social norms and environmental and social challenges, with constant or more frequent herd mobility to facilitate livestock's year-round access to pastoral resources. Moreover, transhumance is increasingly practised by persons not of pastoral-associated tribes, and there is increasing marked expansion of crop cultivation among traditional pastoralists. Such ongoing changes in pastoral systems may compromise the resilience and sustainability of farming systems (Houessou et al. 2019).

In the agro-pastoral system, farmers grow crops in addition to keeping livestock. The pastoral and agro-pastoral systems are based on the use of natural or semi-natural vegetation. Local practices and knowledge are of great value in these systems to effectively manage a diversity of breeds and their roles and the feeding environment and resources. For example, in the transhumance system, herders move their animals from dry areas during the dry seasons to areas with green pasture for the survival of the animals, and knowledge of the routes and areas with adequate pasture and water is necessary. About 60% of the land area of SSA is covered by rangelands with predominantly native (uncultivated) grasses, grass-like plants, shrubs, woodlands and savannahs suitable for grazing or browsing by domestic and wild animals. The SSA rangelands support a population of more than 100 million pastoralists (Notenbaert et al. 2009). The agro-pastoral areas cover about 19% of the land in SSA, are home to almost 10% of the population and house more than 15 million cattle. One-third of the pastoralists is estimated to be under an agro-pastoral management system involved with livestock and crop production.

Main livestock and products The main livestock species raised under pastoral systems of management are cattle, goat, sheep, camel and donkey. The main products are meat, milk and hide/wool. Although the main reason for keeping livestock under pastoral systems is subsistence, social and cultural functions are also important.

Challenges Challenges related to changes in land use, climate change, fodder availability/quality, grazing reserves, water shortages, disease outbreaks and conflicts with settled farmers are common in pastoral systems. The perennial movement of transhumant cattle from Sahel regions to the coastal regions of West Africa, in particular, in recent times, often leads to conflicts between the livestock herders and resident crop farmers as a result of the shrinkage of land for

feeding and watering, lack of well-defined grazing corridors and a general failure of countries to adhere to the Economic Communities of West African States (ECOWAS) protocol on transhumance. These challenges have negative implications on the implementation of strategies for sustainable livestock genetic improvement, being compounded by small herd sizes without proper identification, variability between farms and uncontrolled breeding. Most African government policies towards solving the problems associated with pastoralism are often directed towards resettlement rather than actively addressing the issues directly. Pastoralists are, however, adopting new practices that enhance the productivity of their animals. For example, communication technology such as mobile phones is providing greater access to markets and meteorological information, thereby adding further benefits. With the use of mobile phones, the market price of livestock (cattle, goat, sheep or camel) is easily available, and combined with weather information (forecast), pastoralists/agro-pastoralists are able to be in control of the time to sell their stock or move to specific grazing lands.

To solve the problems associated with overgrazing of rangelands, climate change and pressure on transhumance routes, agro-silvo-pastoral systems of livestock management are gaining importance in Africa. In this system, livestock benefit from grazing pasture and woody perennials and the shade provided by the trees, while the trees benefit from soil fertilisation by animal waste and the improvement of biodiversity.

2.3.1.2 Smallholder Mixed Crop–Livestock Systems

This system constitutes the backbone of animal agriculture in Africa, within which about 70% of livestock is produced. The mixed crop–livestock system includes smallholder extensive subsistence and intensive commercial systems and medium-scale intensive commercial systems. The term 'smallholder' is mainly used to describe farmers or producers with limited resources (resource-poor or subsistence farmers) such as land, labour, capital and feed inputs. In this system, at least 15% of the land is used for crop cultivation, and over 10% of animal feed (dry matter) is derived from crop by-products or stubble and grazing. Based on rainfall, this system is further classified into mixed rain-fed and irrigated systems. The rain-fed system is dominant, whereby animal production is dependent on rainfall to grow the feed/grazing and water the animals. The major species kept within this system are cattle, buffalo, sheep, goat, poultry and pig, while the major crops cultivated are maize, millet, rice, sorghum, pigeon pea, groundnut, soybean, banana, cocoa, coffee, cotton, palm, casava and vegetable crops. This system is common in the tropical highland, semi-arid, humid and sub-humid regions. In mixed irrigated systems, about 10% of the arable land is irrigated for crop production and for watering animals. The mixed irrigated system is practised in semi-arid and arid regions where rainfall is a major limitation for crop cultivation; therefore, irrigation ensures year-round crop production for use in animal feeding and watering. Irrigation, therefore, supports increased fodder production/availability, which lessens feed deficit and makes the intensification and commercialisation of livestock production in urban and peri-urban areas feasible (Dixon et al. 2001; Thornton et al. 2002).

The diversity in mixed systems enables positive synergies between crops and livestock, such as the recycling of animal waste and crop residues, and a multifunctional use of livestock (Fig. 2.5). Fifteen crop–livestock farming systems (Table 2.4) identified in SSA by Dixon et al. (2001) were based on several factors, including (1) the availability of natural resources, which include water, land, grazing area and forest; (2) climate, of which altitude is an important determinant; (3) landscape including slope; (4) farm size and tenure in relation to access to different resources; (5) dominant farm activities and household livelihood patterns (e.g. crops, livestock, trees, aquaculture, hunting and gathering and off-farm activities); (6) technologies and the resulting intensity of production and integration of crops and livestock; and (7) farm management and organisation (e.g. family, corporate, cooperative, etc.). Rain-fed crop production combined with livestock production occupies about 20% of

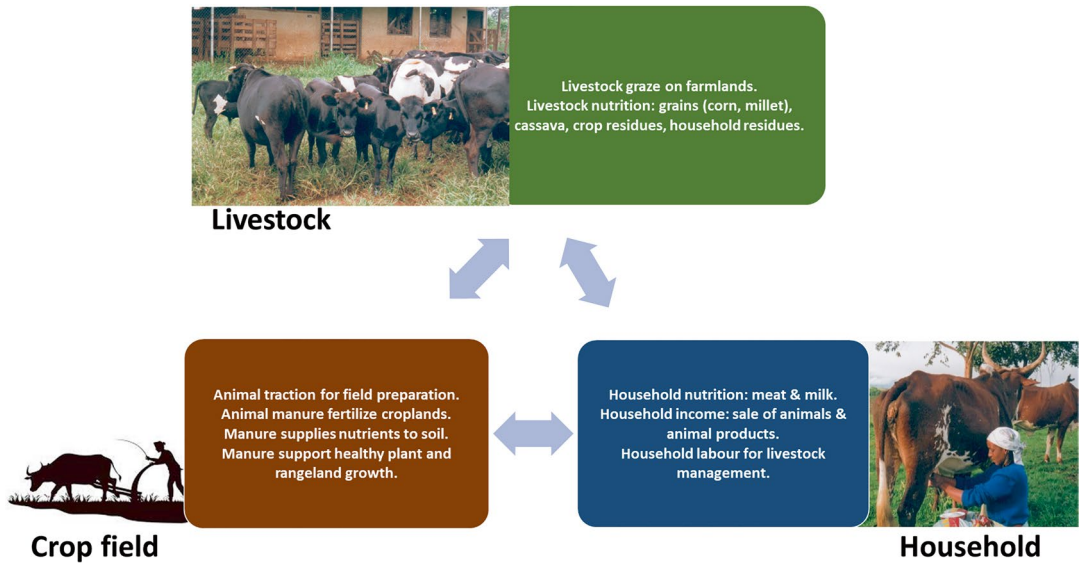

Fig. 2.5 Positive synergies between crops, livestock and households in mixed crop–livestock systems

the land area in SSA (Notenbaert et al. 2009). The cropping systems where cereals dominate occupy most of this area (12%), followed by tree crops (3%) and legumes (2%). Large-scale irrigation is rare in SSA, with only 0.1% of the land area under such management supporting a fraction of the human as well as animal population.

Smallholder Extensive Mixed Crop–Livestock Production Systems

Characteristics The smallholder mixed livestock production systems are extensive subsistence systems with the main production objective of meeting the needs of the farm family with no immediate objective of making a profit out of the sale of animals and animal products. Little or no investment is put into the operations (no hired labour), but it depends on family or close relatives for animal management. There is little or no formal record-keeping, although in some cases, farmers have their own unique ways of identifying individual animals and determining their productivity and market value. For ruminant production, the free-range system is mostly practised with farmers relying on communal grazing lands to feed their stock. Mixed farming is a common feature with two or more livestock species or breeds kept. Animals are fed on various agricultural by-products. The availability and the nutritional plane of agro-industrial by-products and communal pastures vary depending on the season, and this has a bearing on the growth and productivity of livestock. Under this system, pig feeding often relies on household waste and leftovers from restaurants and other food service providers.

Farmers in this system also grow crops, often sharing their attention between crop production and livestock management. For instance, smallholder cattle production in West Africa is extensive and dominated by indigenous cattle breeds with the ability to adapt to the local environment, such as Somba, Lagune, Muturu, N'Dama, Kuri, Gudali, White Fulani, Red Fulani, Ghana Sanga and Borgou, among others. They also have adaptive traits including but not limited to tolerance to ticks and tick-borne diseases, heat and diseases such as trypanosomiasis (Adido and Gicheha 2018). Animals are housed in backyard fencing made from local materials or housed indoors, with little or no investments in nutrition and healthcare. In this system, poultry and pigs are also raised under free-range small-extensive/extensive scavenging systems with 1 to 50 animals per family. Poultry and pig feed by scaveng-

Table 2.4 Major mixed crop–livestock farming systems of sub-Saharan Africa described by Dixon et al. (2001)

Farming systems	Land area (% of region)	Agriculture population (% of region)	Principal livelihoods
Irrigated	1	2	Rice, cotton, vegetables, rain-fed crops, cattle, poultry
Tree crop/crop	3	6	Cocoa, coffee, oil palm, rubber, yams, maize, off-farm work
Forest-based	11	7	Cassava, maize, beans, cocoyam
Rice-tree crop	1	2	Rice, banana, coffee, maize, cassava, legumes, livestock, off-farm work
Highland perennial	1	8	Banana, plantain, coffee, cassava, sweet potato, beans, cereals, livestock, poultry, off-farm work
Highland temperate mixed	2	7	Wheat barley, teff, peas, lentils, broad beans, potatoes, sheep, goat, livestock, poultry, off-farm work
Root crop	11	11	Yam, cassava, legumes, off-farm work
Cereal-root crop mixed	13	15	Maize, sorghum, millet, cassava, yam, legumes, cattle
Maize mixed	10	15	Maize, tobacco, cotton, cattle, goat, poultry, off-farm work
Large commercial and smallholder	5	4	Maize, pulses, sunflower, cattle, sheep, goat
Agro-pastoral millet/sorghum	8	8	Sorghum, pearl millet, pulses, sesame, cattle, sheep, goat, poultry, off-farm work
Pastoral	14	7	Cattle, camel, sheep, goat, remittances
Sparse (arid)	17	1	Irrigated maize, vegetables, date palm, cattle, off-farm work
Coastal artisanal fishing	2	3	Marine fish, coconut, cashew, banana, yam, fruit, goat, poultry, off-farm work
Urban-based	<1	3	Fruits, vegetables, dairy, cattle, goat, poultry, off-farm work

ing, with little or occasional supplementation with kitchen waste. During the cropping season, pigs are tethered to protect the crops and farmlands from destruction.

Main Species and Products Most indigenous chicken, pig, cattle, sheep and goat breeds are raised in this system. The main products are live animals, milk, meat and eggs.

Challenges The main challenges faced by this system include high mortality rates due to the lack of veterinary attention and medications. Farmers in this system also have limited knowledge of modern animal-farming methods. Consequently, animal productivity is low in the smallholder extensive mixed crop–livestock production system.

Free-Range Livestock Production System

Characteristics Animals roam freely and scavenge for food and water. Supplementary feeding with kitchen waste is offered when it is available. Some form of backyard housing is provided for shelter during the night. No form of disease management is practised in this system. Indigenous chickens are mostly raised under this system, and pig is raised to a lesser extent. Consumer perception is that free ranging provides greater opportunities for livestock to express their natural behaviours, resulting in improve welfare (Campbell et al. 2021). Moreover, free ranging in chicken has been linked to health benefits such as improved plumage condition, reduced pecking and reduced diseases such as footpad dermatitis (Campbell et al. 2021).

Main species and products Livestock species commonly raised under the free-range system are poultry and pig. The main products are live animals, meat and eggs.

Challenges Health risks associated with free-range systems include greater susceptibility to diseases and parasites. Animals are exposed to predation, rainfall, heat stress and other environmental challenges. Productivity in this system is low.

Smallholder Commercial Intensive/ Semi-intensive Livestock Production Systems

Characteristics This system is labour-intensive and often uses family labour. Smallholder intensive livestock farming is combined with low-input rain-fed crop production. This system can be found in peri-urban areas and marginalised or isolated areas. Requirements for this system include diverse inputs and labour. Inputs are sourced from local/natural resources such as crops and industrial by-products, grains from own farms and kitchen waste. Figure 2.6 shows small, intensively managed backyard pig and poultry farms. Production is for commercial purpose (local markets), home consumption and non-monetary exchange (e.g. as payment for school fees). Animal waste (manure) is used as the input for crop production.

Producers usually invest in improved management practices such as housing, animal healthcare, improved feeding and the use of improved breeds such as exotic as well as exotic × local crossbreds (chicken, pig and dairy cattle). Herd

Fig. 2.6 Small intensively managed backyard pig farm (**a**) and poultry farm (**b**) in Bambili, Cameroon. (Photos by Azenui B. Abongban)

sizes could be up to 50 (pig) or 200 (poultry), and productivity is higher, and the products are sold in local markets.

Main species and products Cattle, goat, pig, poultry and sheep are raised in these systems and often involve less animal mobility. High-yielding exotics and their crossbreds with indigenous livestock species are also kept in this system. The main products include live animals, meat, milk, eggs, skin and hide.

Challenges Challenges of this system include limited access to information and technologies, poor infrastructure, high cost of inputs (feed, drugs, etc.) or lack of inputs, high disease burden, limited access to markets, limited marketing channels for products or the lack of appropriate marketing channels, limited attention by policymakers, limited research or extension education, environmental factors and climate change.

2.3.1.3 Urban and Peri-urban Livestock Production Systems or Landless Production Systems

The urban and peri-urban livestock systems are generally regarded as landless production systems on small pieces of land, mainly household backyards and yards not demarcated for the keeping of livestock.

In this system, about 10% of the dry matter fed to livestock is farm-produced or kitchen waste, and the average livestock density is 14.6 tropical livestock units (TLU)/km^2. This system is found in all agro-ecological zones where land is a constraint and livestock feeding depends on external feed resources. In West Africa, it is the most fragmented in terms of spread, covering an area of 52,642 square km (Fernández-Rivera et al. 2004). The system can be further classified as landless small subsistence and smallholder commercial intensive/semi-intensive peri-urban systems. In general, smallholder landless producers keep animals for multiple purposes in backyard settings, while the commercial intensive/semi-intensive peri-urban systems are demand-driven and specialise in meat, egg or milk production.

Peri-urban poultry and pig production are commercially oriented and intensively managed to ensure rapid growth to meet the demands of urban dwellers. Stocking rates could reach 10,000 birds with the provision of adequate housing, feeding, healthcare and waste disposal systems. Figure 2.7 shows a medium-scale, commercially and intensively managed poultry farm in Nkwen, Cameroon. Dairy cattle, goat, pig and rabbit (mainly exotics and crossbreds) are kept under intensive (stall-feeding) or semi-intensive (backyard/tethering) systems, either as livestock-only or with small-scale crop production. In particular, peri-urban dairying (cattle and goat) is growing fast in some countries (e.g. Kenya and Ethiopia) due to rising demands in urban centres. Stall-feeding is also practised, mainly for the festival fattening of sheep and poultry, and in some major livestock markets to recondition stock before reselling them, usually at the same market. According to Fernández-Rivera et al. (Fernández-Rivera et al. 2004), stall feeding is a common and long-standing tradition in West Africa, probably rooted in the fattening of sheep, specifically for the Tabaski Muslim festival. The boundaries of the stall-fed urban and peri-urban livestock systems are defined by sites in the region with a human population density greater than 450 persons/km^2. In urban centres, crop and livestock production are spatially separated such that all feed-crop residues, cut-and-carry fodder and other supplementary feeds are imported from outside the stall, thereby limiting the benefit of the producer from the usual crop–livestock interaction. Livestock ration depends on the surrounding crop–livestock system; for instance, a peri-urban system located in Niamey (Niger) will likely depend on feeds from pearl millet–cowpea crops, while in Dakar (Senegal), it will depend on feeds from rice and groundnut crops and in Nigeria, on feeds from corn, cassava, cowpea and groundnut haulms. With the current trends in urbanisation, this system is expected to grow in importance and will encourage its practitioners to grow their own feed to ensure a reliable source of nutrition for their livestock.

Fig. 2.7 A peri-urban medium-scale, commercial, intensively managed poultry farm in Nkwen, Cameroon. (Photo by Azenui B. Abongban)

Main Species and Products The common livestock species for these systems are pig and poultry, though cattle and other large stock can be kept. The main products are live animals, meat, milk and skin/hide.

Challenges Major constraints of the urban and peri-urban production systems border on the high cost of inputs, health management, waste disposal and issues of sanitation, particularly in intensive farms near populated cities, with implications on public and environmental health, especially with the expansion of the more market-oriented aspects of the system.

2.3.2 Large-Scale Livestock Production Systems

Large-scale systems include extensive pastoral systems (discussed above), commercial ranching and intensive systems. The commercial ranching and intensive systems are capital-intensive in nature and typically linked with highly controlled environments where land and labour inputs have been maximised through intensification and mechanisation with heavy capital investment. These systems are characterised by high labour inputs in terms of housing, machinery, feeding, genetics, healthcare and labour. Chicken, pig and, to a small extent, dairy animals (cattle and goat) are popular in these systems in Africa, and the main goal of production is cash income. Intensive commercial livestock production systems are mostly located close to urban centres.

2.3.2.1 Large-Scale Extensive Commercial Ranching Livestock System

Large-scale extensive commercial system or ranching represents a relatively small but critical proportion of the production systems on the

African continent (AU-IBAR 2019). Ranching is considered an improvement or modernisation of the pastoral/agro-pastoral systems. In the ranching system, land is owned by individuals, commercially organised groups or government-run institutions. In the southern region of the continent and in some countries of East Africa, robust programmes for selective breeding and improvement of indigenous breeds are managed within these systems. This has greatly contributed to the production of specialised indigenous livestock breeds such as the Boran and Tuli cattle for beef production in East and Southern Africa, local indigenous pig breeds like the Ashanti dwarf pig for pork production in Central and West Africa, the Boer goat for chevron production in Southern Africa, Barki and Beni Guil sheep for mutton in North Africa and chevron production from West African Dwarf goat in West and Central Africa.

Ranching is a labour-extensive undertaking, specialising in the production from one or two livestock species of a marketable commodity, mainly live animals for slaughter for meat, skin and hide but also wool and milk. The function of livestock is mainly to provide cash income. Livestock management is characterised by grazing within fixed boundaries by individual tenure with the intensification of possibilities for feeding and watering.

Fenced feed-lots are incorporated in most ranches to finish livestock to a desired market weight and meat quality faster. Feed-lots can be either dry lots where grain-based rations are used or more extensive, involving grass-fed growing operations. There is limited diversity of livestock within the ranching system, and animals are kept for specific purposes such as meat quality. The ranching system is characterised by high inputs in terms of pasture management, health management, crop production for supplemental feeding and a high level of mechanisation. The forms of ownership may be parastatal, cooperative or private (companies or individuals), and instead of straightforward ownership, there may be lease arrangements. Individual tenure means tenure by the individual ranch system where many management units share the tenure of the land. In present-day Africa, ranching is mostly practised by research institutions (government and private), universities and, to a limited extent, the private sector.

Ranching is increasingly being adopted to address frequent farmer–pastoralist/herder conflicts in many African countries. Recently, Ghana adopted a national cattle ranching policy to establish ranches as solutions to farmer–herder conflicts in the southern region of the country due to transhumance by Fulani herdsmen from the North and Sahelian countries. However, complex land tenure arrangements, identity perceptions of Fulani herders (generally perceived as dangerous, murderous and violent), perceptions of land grab and dynamics of access to animal feed and water sources could make cattle ranching less feasible, thus calling for better understanding of the nature of conflicts and widening public consultation, which will support a ranching policy that is feasible (Ahmed and Kuusaana 2021).

Main Species and Products Livestock species reared in this system include cattle, sheep, goat, camel and buffalo. Locally adapted exotic animals, indigenous breeds and crosses between them are reared for commercial production of meat, milk, hide and skin in the ranching system.

Challenges The main constraints include limited land availability, high costs of inputs (feed, disease management and infrastructure) and changing climatic conditions.

2.3.2.2 Large-Scale Intensive Commercial Livestock Production Systems

These are capital-intensive systems characterised by highly modified environments where land and labour inputs have been replaced with adequate mechanisation and technology (FAO 2018a). In many African countries, poultry and pig are the main species raised in this system. Intensive dairying and beef production (ranching) are also common in some African countries (e.g. South Africa). Poultry farms of this system are large, and some are highly mechanised and extremely

productive. With the supply of genetically improved poultry breeds by big companies (e.g. Aviagen, Hendrix Genetics, Hubbard, etc.) producing highly productive poultry strains, intensive commercial poultry production is growing rapidly in many African countries and, with this growth, is the emergence of poultry farmer associations (e.g. Poultry Association of Nigeria [PAN], Ghana National Association of Poultry Farmers, Kenya Poultry Farmers Association, etc.) to support the interest of farmers and find markets for products. For example, membership categories of the Poultry Association of Nigeria include micro-farmers (<2000 birds' capacity), small farmers (2000–10,000 birds), medium farmers (10,000–50,000), large farmers (50,000–200,000) and mega-farmers (>200,000 birds), which testifies to the scale of operations. PAN helps its members maintain a sustainable poultry sector through services like (1) education (poultry education, conducting of and/or assistance in investigative work of a practical and scientific nature and organisation of seminars and courses); (2) advance improvement of poultry production by embracing and coordinating production objectives (egg, broiler, chicks, etc.); (3) coordination of the aims, views and efforts of poultry operators; and (4) protection of the poultry industry from adverse policies and legislation and assistance in obtaining beneficial legislative policies and regulation, among others. Through the activities of the union, farmers are better informed on management practices, housing, healthcare, marketing and acquisition of inputs. Thus, intensive poultry and pig production, which have been the mainstay in high-income countries, are becoming more prevalent in African countries, where they are supplying much-needed animal proteins to feed fast-growing urban populations. These intensive poultry and pig farms are highly efficient as well as extremely productive (Fig. 2.8). For example, Obasanjo Farms (Obasanjo Farms, Ota, Ogun state, Nigeria) operates, among others, a large-scale, intensively managed poultry farm specialising in producing both egg and broiler. Obasanjo Farms is a big player in the Nigerian poultry industry, with a capacity of about 1.3 million meat chickens and 1.26 million laying hens with the ability to produce 20,000 creates of eggs per day. Obasanjo Farms is highly mechanised in its operations, produces its own feed, and processes its broiler birds. Its broiler-processing plant processes up to 2500 chickens per hour. In addition to poultry production, Obasanjo Farms also engages in pig, rabbit, snail, fish and dairy (cattle) production.

Main Livestock and Products The main livestock raised in this system are poultry and pig. The main products are meat, egg and manure.

Challenges Intensive livestock production systems are faced with multifaceted challenges such as the high cost of inputs, limited access to high quality genetics, high cost of drugs and veterinary care, high cost of feeds, unstable electricity and water supply, unstable marketing channels, emergence of antimicrobial resistance due to high use of antimicrobials, high cost of production and environmental impacts through deforestation to set up large farm buildings, disruption of nutrient cycles and pollution with pesticides.

2.3.3 Livestock System Production Highlights of Some African Countries

Within countries, regions and the continent, there is great diversity in the livestock production systems presented above in terms of the level of development and dominance of the different livestock sub-sectors, such as dairying, pastoralism and wool and meat production. For example, pastoralism is mainly practised by certain tribes in East, West and Central Africa. While smallholder dairy production is growing in importance in East Africa, intensive dairy production is common in Southern Africa. In West Africa, smallholder poultry and ruminant production systems are commonplace, and small-intensive to large-scale, intensive poultry and pig production systems are becoming popular. Differences in the production systems for the various species are shaped by the inherent specific geographic and environmental

Fig. 2.8 Large-scale, intensively managed poultry operations: (**a**) broiler, (**b**) layer, (**c**) meat processing and (**d**) chick units at commercial farms in Nigeria

challenges and, to some extent, religious perceptions. For example, pig production is not practised in Northern Africa (except Egypt) for religious reasons. To provide more clarity, the country-specific production systems for poultry (Nigeria), cattle (Kenya) and buffalo (Egypt) are highlighted below.

2.3.3.1 Chicken Production System Highlights of Nigeria

The Nigerian poultry industry is the second largest (after South Africa) in Africa, with over 180 million birds producing about 454 billion tonnes and 3.8 million tonnes of meat and eggs, respectively, with about 80, 60 and 40 million birds raised in extensive, semi-intensive and intensive systems, respectively (Mcdougal 2019). In 2021, its egg production of 14.43 billion eggs was the highest in Africa, followed by South Africa (10.36 billion eggs) and Egypt (10.32 billion eggs) (FAOSTATS 2022). Poultry meat and eggs are unrestricted by any religion or culture in Nigeria, making them the most consumed animal proteins in the country. The poultry sector is the most commercialised livestock sector in Nigeria, accounting for ~8% of Nigeria's gross domestic product (GDP) and ~30% of the total agriculture contribution. It provides about 14 million jobs and accounts for about 58.2% of Nigeria's animal production (Ogunyemi and Orowole 2020; Heise et al. 2015; FAO 2020b).

Three major poultry production systems are practised in Nigeria and include the extensive (free-range), semi-intensive and intensive systems. In 2017, 83.4 M, 58.4 M and 38.4 M birds were found within the extensive, semi-intensive and intensive systems of production, respectively.

(a) *Free-range (extensive) system*: Nearly 50% of chicken production in Nigeria takes place under the free-range or backyard subsistence-oriented system. Birds kept are often of different indigenous breeds and varying ages. Birds are left to scavenge for food and water. Kitchen leftovers and agricultural by-products are provided when available. At night, birds roost outside in trees or nest in bushes close to the farmer's dwelling. In some cases, some form of housing in the form of wooden cages may be provided in the backyards. There is little or no attention in terms of disease management. Productivity is low and characterised by low body weights, longer time to reach maturity and low egg productivity of about 50–65 eggs/hen/year. The average flock size is about 50 birds. Due to the limited or no provision for housing, free-range chickens are exposed to predators, climate and weather stress and high disease burden, with Newcastle disease being the most common disease.

(b) *Semi-intensive system*: The semi-intensive system is practised in family-owned farms, and the main production objective is market-oriented. About one-third of the total chicken population in Nigeria is raised under this system. Most semi-intensive chicken farms are located in peri-urban and urban centres for easy access to markets and inputs. The average flock composition includes indigenous and improved breeds, and the herd size ranges from 50 to about 2000 birds. Management includes the provision of housing, feed, water and healthcare and compliance with basic biosecurity measures. Products (live birds and eggs) are marketed through informal channels, mostly to urban dwellers. Productivity levels are low to medium. The main challenges faced are limited access to feed and healthcare due to low purchasing power, low productivity, disease and environmental perturbations.

(c) *Intensive (commercial/integrated) system*: The intensive poultry sector in Nigeria is commercially oriented, having its own great-grandparent and grandparent hatcheries, layers and broiler farms. About 21% of chickens in Nigeria are raised in commercial and/or integrated farms. The sector has a number of fully, vertically integrated commercial operators, which have adequate capital and technical capacity. Optimal housing, feeding and health management practices ensure high productivity of the system. High biosecurity measures are practised, and productivity levels are high. The Nigerian intensive poultry production landscape consists of three typologies of integrated poultry farms: (1) commercial peri-urban enterprises with flock sizes of between 2000 and 5000 birds, (2) clustered commercial enterprises with flock sizes of over 5000 birds and located in peri-urban areas, and (3) large commercial poultry integrators, which own feed mills, hatcheries and processing facilities, with flock sizes of up to 100,000 birds or more. Some of the large poultry integrators are franchisees or have joint ventures with global poultry operators. Poultry are sold to consumers as dressed and processed chicken in large and small retail outlets. The main problems faced are the high costs of inputs and frequent disease episodes such as Gumboro and highly pathogenic avian influenza.

2.3.3.2 Cattle Production System Highlights of Kenya

Kenya, with a cattle population of 22.9 million heads in 2021 (FAOSTATS 2022), has vibrant dairy and beef cattle sectors. The beef industry is the largest contributor to Kenya's agricultural GDP at about 35%, followed by dairy production (Kosgey et al. 2011). In terms of value and employment, the cattle industry is a significant contributor to the Kenyan economy (Alarcon et al. 2017). The dairy sector in Kenya is the second largest in Africa (after South Africa). In 2021, Kenya produced over six million tonnes of milk, of which 77% was from cattle, 18% from camel and 4.3% from goat (FAOSTATS 2022). Milk is primarily produced by smallholder dairy farmers (about 1.8 M smallholder farmers constituting about 80% of dairy producers), who account for about 80% of the total milk production in the country (KMALF 2010).

Dairy Cattle Production Systems

Three dairy production systems have been identified in Kenya and include large- and small-scale intensive, semi-intensive or semi-grazing system and extensive controlled (10% of farms) and uncontrolled (5% of farms) dairy production systems (FAO 2018b).

Large- and Small-Scale Intensive Dairy Production Systems About 40% of farms practise small-/large-scale intensive dairying. This system is characterised by animal confinement with zero grazing, high levels of health and nutrition management and feed resource planning. The system is dominated by small-scale dairy farms (35%), which also grow crops and predominate in Mount Kenya and central Rift Valley regions. Small-scale intensive dairying is also common in urban and peri-urban centres in the sub-humid and humid regions of Kenya. Flock sizes range from one to 20 for small-scale operations to >20 for large scale operations (Nguluu et al. 2011; Staal et al. 2001). The main breeds used are Holstein, Jersey, Fleckvieh, Ayrshires and Guernsey, and the main product is milk.

Feed for animals is either purchased or grown by producers. Regular health management includes regular tick and internal parasite control and vaccination against diseases such as Rift Valley fever, East Coast fever, black quarter/blackleg, lumpy skin disease, foot and mouth disease and anthrax. Other diseases like brucellosis and mastitis are also common. The type of housing is basic or simple. Milk production is primarily for sale as well as for home consumption. While the large-scale farmers sell their milk to large cooperatives and processors, the small-scale producers sell to middlemen cooperatives (KMALF 2010; Staal et al. 2001). The main constraints faced by producers in this system are the high cost of feed ingredients, poor quality feed, high cost of veterinary drugs, inadequate veterinary services, unfavourable policies limiting peri-urban dairying and limited access to credit. Despite these challenges, intensive dairy production in Kenya has the potential for rapid growth fuelled by the increasing demand for milk and milk products.

Semi-intensive or Semi-grazing Dairy Production System This is the predominant dairy production system (45% of dairy farms) practised in areas of greater land availability in Kenya. In this system, herd management includes grazing animals freely or in paddocks during the day and stall-feeding at night and supplemental feeding with concentrates (grain millings or compounded dairy feeds) during milking (Muia et al. 2011; Nguluu et al. 2011). Thus, feeding is on native and improved pastures, post-harvest grazing and concentrates.

Unlike in the intensive system, animals are raised in mixed herds with other livestock species such as sheep, goat, chicken and donkey, as well as pig (Staal et al. 2001). Semi-intensive dairy farms are predominantly found in areas around Mount Kenya, the central and north Rift Valley, the coastal regions and the western and Nyanza areas where crop production is practised. The semi-grazing herds are small in size (about one to 20 animals), and the main species kept are exotic breeds like Holstein, Ayrshire, Jersey, Guernsey and zebu/Zenga breeds like Sahiwal, Boran and small East African zebu. Reproduction management is mostly by natural mating (70% of farms) because artificial insemination (AI) service is not easily available (Staal et al. 2001). Production is relatively low in this system, averaging ≤6 litres/cow/day or yearly production ranging from 1300 to 4575 kg, depending on the availability of feeds, the breed, the production system and the agro-ecological zone (Staal et al. 2001; Muia et al. 2011; Omore et al. 1999; Mugambi et al. 2015). The milk produced is mostly consumed in homes (~40% farmers) or sold in liquid (unprocessed) form through informal channels.

The main constraints of the semi-intensive dairy production sector include low quality and limited availability of feeds, limited reliable statistical information on milk market outlets, poor infrastructure, limited access to credit, limited technical know-how on husbandry practices, limited access to veterinary services and artificial insemination services and high cost of drugs (Odero-Waitituh 2017).

Extensive dairy production system This system is characterised by pasture-based management and is practised in areas with large farms where controlled grazing is possible and on marginal and communal grazing lands where grazing is not controlled. About 3% of farms with ~35% of the dairy cattle population are involved in extensive dairy production (Omore et al. 1999). Herd sizes range from ≤10 animals (uncontrolled grazing) to about 50 or more animals (controlled grazing).

Controlled grazing involves placing animals on natural and improved pastures in paddocks or strip grazing, as well as supplementation with fodder (of high quality), mineral licks and concentrates. On the other hand, uncontrolled grazing involves free grazing of animals on native or improved pastures with limited supplementation. Housing infrastructure (e.g. hay barns, dips, water troughs and crushes) is mostly provided in the controlled grazing system. Disease management is by vaccination, parasite control (mostly in the controlled grazing system) and the uncontrolled use of acaricides and dewormers, which may increase the development of drug resistance. There is a high prevalence of contagious bovine pleuropneumonia in this system, while tick-borne diseases are the major causes of death (Staal et al. 2001; Tambi et al. 2006). The milk production range of 4–11 l per cow per day is relatively low compared to the intensive system (Lanyasunya et al. 2006). The milk and dairy products from this system are considered to be of high quality (organic) due to the limited use of antimicrobials and are sold in niche markets and at good prices.

Beef Cattle Production Systems

Beef cattle production in Kenya is mainly concentrated in the arid and semi-arid lands (ASALs), which host 70% of the national herd and where beef production from pasture is the main economic activity and main source of household livelihoods (Kahi et al. 2006; MSDNKOAL 2012). Three beef production subsystems are recognised in Kenya: extensive grazing (pastoralism and ranching), semi-intensive grazing (agro-pastoralism) and intensive (feed-lot) systems.

Pastoralism-Extensive Beef Production System The pastoralism system (see Section 2.3.1.1) is a low-input, low-output system where animals depend entirely on grazing native pastures or communal grazing lands for their maintenance and productivity. Other forms of pastoralism like transhumance and nomadism are also practised (Kahi et al. 2006; Ouda et al. 2001). Extensive pastoralists are important beef producers, comprising 34% of beef producers but with the lowest livestock densities of 11 TLU/km^2 or an average herd size of 50 animals (FAO 2018b). The cattle breeds in this system are indigenous breeds (small East African zebu, Boran and Sahiwal) kept mostly in mixed herds with other livestock (sheep and goat). Feeding management is based on grazing on native pastures, which is affected by seasonality in rainfall. Therefore, animals are often moved from one place to another in search of pasture and water, resulting in conflicts over grazing rights and water resources as well as conflicts with large-scale ranch operators (Mwangi et al. 2020; Otieno et al. 2012). Disease management through vaccination is low due to the nature of pastoralism and the climatic and infrastructural conditions of the ASALs (Kimani et al. 2016). Brucellosis and tick infestations are of higher prevalence in pastoralism systems (Kadohira et al. 1997). The annual average beef production in the pastoral system is about 408,000 tonnes (about 70% is from the zebu cattle in the ASALs), and the average yield per animal is estimated at 120 kg (Behnke and Muthami 2011). Pastoralist animals are mainly sold live at animal markets (primary and secondary markets), mostly dominated by traders and middlemen. The beef from pastoralist cattle, which satisfies the bulk of domestic demand, is sold to consumers in urban markets (the most important being Nairobi) (Kahi et al. 2006).

The main challenges of pastoral livestock production are drought, erratic weather patterns affecting the supply of feed and water, wildlife attacks, livestock raids, livestock diseases, poor management of pastures, invasive plants, lack of/weak delivery of extension services, limited veterinary services, high cost of drugs and other inputs, poor market infrastructure, low prices and

insecurity and limited prior access to market information (Mwangi et al. 2020; Otieno et al. 2012; Wanyoike et al. 2018; Makokha and Witwer 2013).

Ranching-Extensive Beef Production System
Ranching is not a major beef production system in Kenya, but it is commercially oriented and contributes to most of the beef exports of Kenya (FAO 2018b). Ranching is practised by 11% of farms, which are made up of large land areas and have large herd sizes (average of 150 animals). The majority of ranches are privately owned and are predominantly found in Laikipia and Taita Taveta counties. A few government ranches are spread across the sub-humid and semi-arid zones of Kenya. The main breeds raised are exotic (Hereford, Simmental, Charolaise and Angus), improved Boran and exotic × Zebu crosses (Kosgey et al. 2011; Mwangi et al. 2020; Otieno et al. 2012; Khalil and Sammour 2006). Ranching is fairly labour-intensive, using specialised professional and unskilled labour. Infrastructure for disease control, feeding and water storage are available at most ranches. Feed management includes grazing on natural and improved pastures with some feed supplementation. The main diseases are parasitic (worm and tick infestations), which are controlled through regular deworming and dipping, as well as brucellosis and tuberculosis, which are controlled with antibiotics. The beef from the ranches is sold at local niche and international markets. Most ranches (70%) have access to marketing information, and >75% of them sell live animals to abattoirs, mostly (53%) by regular contract (Otieno et al. 2012).

The main constraints of beef cattle ranching include high feed cost (especially during the dry season), drought, difficulties in targeting and reaching affluent markets, low and fluctuating livestock prices, recurrent conflicts with pastoralists in search of pasture and water, wildlife attacks, disease challenges due to livestock–wildlife interactions, lack of government support and the unavailability/high cost of livestock drugs (Mwangi et al. 2020; FAO 2018b).

Semi-intensive Grazing System or Agro-pastoralism
Agro-pastoralism (see Sect. 2.3.1.2) is a low-input, low-output system where producers keep livestock and also grow crops. The production system is subsistence-oriented and is mostly practised in the semi-arid areas of the country. Generally, agro-pastoralism is practised in more regions of Kenya (coastal, lower eastern, north and south Rift) and on more farms (54%) when compared with other systems. Animal densities are low ranging from 20 TLU/km^2 (lowlands) to 50 TLU/km^2 (highlands), with average herd sizes from ten to 12 animals, with the main animals being crossbreds (exotic × zebu crosses) and pure exotic breeds (Otieno et al. 2012; Mwangi et al. 2020). Animals are predominantly fed through grazing on communal lands or in paddocks (where agro-pastoralists have large amounts of land) and supplemented with crop residues. Disease management is achieved through public veterinary vaccination and deworming services. Occasional tick control and treatment of sick animals with drugs from both formal and informal outlets are practised. Major diseases of livestock in the system are parasitic diseases, brucellosis and tuberculosis (Fèvre et al. 2017). Housing are enclosures known as bomas and are provided at night. Livestock products are live animals (and milk) marketed through channels that comprise middlemen or livestock traders at local markets and with links to abattoirs (Otieno et al. 2012).

The main challenges faced by the agro-pastoral system include seasonal variations in pasture and water availability, which result in fluctuating productivity, risk of mycotoxin contamination of poorly stored crop by-products, high disease burden, high cost of veterinary drugs and limited veterinary services.

Intensive Feed-Lot Beef Production Systems Feed-lot (see Sect. 2.3.2.1) is a commercially oriented beef production system in which animals are kept for a limited period of time (~3 months) for fattening using highly nutritious diets. Only about 1% of farms are considered feed-lots and are operated by individual farmers, livestock traders or corporate compa-

nies. Feed-lot operations are both capital- and labour-intensive in terms of infrastructure, labour and inputs, including optimal biosecurity practices and veterinary service practices. The feed-lots are focused on fattening either dairy culls/dairy bull calves or beef breeds. While beef feed-lots could be located anywhere in the country (major commercial feed-lots are found in Nakuru County, Nivasha (keeping up to 3000 animals) and Nyeri County, Kieni (keeping ~500 animals)), dairy cull/bull calf feed-lots are mainly located in the central Rift Valley and Mount Kenya regions (FAO 2018b). Beef breed feed-lots are large and may reach several hundreds of Sahiwal, Boran, small East African zebu and zebu crosses, and specialised beef breeds (Charolaise, Angus and Frisian). Healthcare management includes regular vaccination and deworming and appropriate treatment of sick animals. The primary product is beef, which is sold through formal channels to niche national urban and export markets.

The main constraints are the lack of capital and investment capacities, which limit the expansion of feed-lot systems; animal concentration and issues with dung disposal, which may cause soil, water and air pollution.

2.3.3.3 Buffalo Production System Highlights of Egypt

The bovine sector in Egypt is composed of cattle and buffalo, and it is well-integrated with crop production since the country has limited natural pastures. Female bovines are used for milk production, while males and infertile females are fattened for meat. Bovine (cattle and buffalo) constitute about 23% of Egypt's total agricultural value of 73.5 billion EGP, of which 66% is from meat production and 34% is from milk production (FAO 2018c). The Egyptian buffalo (*Bubalus bubalis*), which belongs to the river type, plays vital roles in the Egyptian economy, serving as a source of food security, an income generator and a source of employment. The Egyptian buffalo supplies the local market with 44% and 39% of its milk and red meat needs, respectively (Fahim et al. 2018).

Egyptian buffaloes are mainly kept in the northern Delta (~57%) and mid-upper (about 43%) regions of Egypt and mostly under traditional mixed crop–livestock farming system (Galal and Elbeltagy 2006; Khalil and Sammour 2006). The main buffalo production systems in Egypt include smallholder mixed crop–livestock/extensive, semi-intensive and intensive production systems.

Smallholder Mixed Crop–Livestock or Extensive Production System This system is characterised by traditional management practices integrating buffalo (bovine) keeping with crop production. It is a low-input, low-output system with limited investments in terms of housing, feeding and health management. Herd sizes range from one to ten, and mainly indigenous breeds of buffalo and cattle are kept, constituting about 33% of the total cattle and buffalo population in Egypt (FAO 2018c). This system is recognised as a major component of rural household livelihood, serving as a source of income and protein in the diet. The key forage crop for feeding animals is Egyptian clover (*berseem*), in addition to corn leaves (*darawa*), hay and straw offered during the summer months. The milk production per animal is low and mostly for home consumption and to feed calves, with excess sold to milk collectors or processed into cheese and ghee and sold at local and urban markets. Another source of income in this system is the sale of surplus calves, unproductive females or cows and bulls, mostly as live animals. Animals in this category are also slaughtered during special occasions like weddings and religious festivals. The animal healthcare management service for this system is during government mass vaccination campaigns against foot and mouth disease, Rift Valley fever and lumpy skin disease.

The main constraints of the extensive production system are poor management and breeding practices, low productivity and profitability, low inputs and outputs, limited access to veterinary drugs/services and extension services, etc.

Semi-intensive Production System It accounts for about 60% of the bovine (cattle and buffalo) population, with herd sizes ranging from ten (cattle) to more than 50 (buffalo), and supplies about 70% of the total domestic milk production and the majority of the meat production (FAO 2018c; Abdel-Salam and Fahim 2018; Abdel-Salam and Fahim 2018). Animal management utilises some modern production and husbandry practices including grazing and the provision of agricultural by-products and animal health services rendered by private veterinary practitioners and regular veterinary services, with constrained access to governmental veterinary services. The main governmental veterinary services received are during mass vaccinations against Rift Valley fever, foot and mouth disease and lumpy skin disease. The milk produced is sold principally as liquid raw milk, while a small percentage is processed into homemade butter, cheese and yoghurt. The milk is principally for home consumption. The surplus milk is sold to milk collectors and distributors for supply to large cities. Some large milk and milk-processing factories also get their supply from this system.

The challenges of the system include varied production practices, a scattered and unorganised farmer community, limited veterinary and extension services, high cost of drugs, limited infrastructure, unregulated value chains, lack of clear marketing channels, limited farmer incentives and high disease burden.

Intensive Buffalo Production System The intensive production system is a high-input, high-output system, accounting for over 7% of the total beef and dairy cattle and buffalo population of the country. This system is made up of large commercial farms with herd sizes from ten to over 1000 animals and accounts for ~4% of the total buffalo and cattle populations, producing ~30% of the marketable milk in the country (FAO 2018c; Abdel-Salam and Fahim 2018). Animals are kept under intensive feeding regimes at commercial farms for the production of regular and/or high-fat milk and at experimental farms for educational (training) and research purposes. The intensive system produces about 84,000 tonnes of meat and 5 million tonnes of milk per year. About 90% of the milk produced is sold to milk processors or milk collection centres, while beef animals are sold to butchers in large cities or directly to slaughterhouses through formal channels. This system enjoys regular access to veterinary and extension services, including vaccinations against endemic and infectious diseases such as brucellosis and government vaccination programmes for Rift Valley disease, foot and mouth disease and lumpy skin disease. The main constraints of the system are the high cost of imported feed ingredients (grains, milling by-products, minerals, vitamins, fats/oils, etc.) and other nutritional supplements.

2.4 Challenges and Interventions for Livestock Development in Africa

Livestock production systems in Africa are faced with numerous challenges including inappropriate policies, poor or low input supply including extension and veterinary services, poor nutrition and limited sources of funding. Additionally, weak institutional and human resource capacities, low private sector participation and conservative farmers often unwilling to try innovations are major limiting factors to developing sustainable animal production practices in Africa. Table 2.5 summarises these major challenges and possible interventions for improved productivity.

2.4.1 Farm Management Practices, Farmer Perceptions and Low Productivity

The current African livestock production is practised to fit local conditions within varied management systems characterised by low/inferior inputs (including genetics) and low outputs and heavy disease burden. Also, most of the extensive and mixed farming systems for many years were not considered serious businesses but secondary activities to crop production handed down

Table 2.5 Major challenges limiting animal performance under current livestock production systems and possible solutions for the sustainable development of improved livestock productivity

Challenge	Possible intervention
Limited knowledge of appropriate production practices that increase animal performance, output and farm incomes	Training of animal owners under the various production systems and other stakeholders including livestock production experts, livestock processors, veterinarians, policy makers and other players along the animal resources value chain on improved management practices and exploitation of livestock for income generation
Poor management practices such as non-identification of animals, variability between farms, uncontrolled breeding, no application of intentional breeding of livestock and high mobility of pastoral flock	Training of livestock keepers on the importance of proper management practices, training on basic animal breeding practices, organising livestock production systems such as cooperative farming and community breeding, formation of national breed societies with regulatory agencies
High disease burden and threat of emerging diseases, limited access to drugs/high cost of drugs and limited veterinary services	Exploration of traditional methods for disease control, training of more veterinarians and provision for free or subsidised veterinary services and medication, increase in funding for research on livestock diseases, breeding for disease resistance and climate change adaptation, and training of farmers on improved management practices
Poor quality and limited availability of feed resources and grazing lands to support improved animal performance	Putting in place grazing land policies that favour access to pasture and pasture development, training of farmers on pasture management and training of animal nutritionists, animal feed producers and extension workers on effective delivery of services to farmers
Frequent clashes between pastoralists and crop farmers	Performance of appropriate consultations between concerned parties to put in place enabling and sustainable solutions to enable access to grazing lands by pastoralist farmers, and putting in place appropriate grazing land policies
Poor production capacity of local breeds under existing production systems and limited information on production characteristics of indigenous breeds	Training of farmers on improved management practices including how to monitor and measure animal performance, undertaking of systematic characterisation of animal productivity in the various production systems for informed decisions on the implementation of improved management strategies, establishment and support of sustained long-term breeding and improvement programmes, systematic characterisation of existing animal genetic resources and conservation through sustainable use and through in situ and ex situ conservation strategies
Lack of appropriate government policies that support gainful exploitation and protection of indigenous livestock	Putting in place government policies that support the gainful exploitation of indigenous livestock breeds; defining the roles of various stakeholders (e.g. NGOs, research, private sector, etc.); strengthening of the linkage between animal research, farmer challenges and extension services; putting in place appropriate incentives and structures for digital animal agriculture by national governments; farmer sensitisation on the use of appropriate technologies to improve farming practices and increase animal performance; resourcing of national agricultural extension systems; private sector involvement to deliver livestock extension services

(continued)

Table 2.5 (continued)

Challenge	Possible intervention
Limited attention and financial support of livestock production and marketing activities by governments	Need for governments to understand the contributions of livestock production to the livelihoods of the people and the national gross domestic product and input in place the necessary funding to support sustainable livestock production, markets and marketing channels; intentional funding of animal research and encouraging the private sector to support government initiatives; concerted efforts required to educate and change the orientation of national policymakers towards funding livestock-related research and increased funding by the government and the private sector
Limited private sector participation in promoting improved livestock production practices	Need for private sector involvement in promoting and funding improved livestock production practices for the benefit of all stakeholders
Lack of appropriate marketing channels/markets for livestock products	Educate farmers on the business aspects of livestock production, establishment of the necessary markets/marketing channels and infrastructure, establishment and support of farmers to run animal markets, modernisation of the livestock trade, putting in place measures to achieve global sanitary and phytosanitary standards, which will stimulate Africa's exports of livestock products
Inappropriate livestock policies, lack of necessary infrastructure for routine recording of production and health traits and limited research facilities, leading to inadequate performance and performance recording	Development of appropriate policies, institutional and legislative frameworks to modernise African livestock production systems; establishment of national/regional recording and improvement schemes to support production practices; upgrade of infrastructure and increase in research funding
Low genetic potential of indigenous livestock breeds and limited information on breed characteristics	Undertaking of massive characterisation (production and genetic potentials) of indigenous livestock breeds, undertaking of intentional breeding programmes for improved productivity of indigenous breeds and training of farmers to do the same, provision of funding to support the characterisation of production systems and the preservation of indigenous breeds for future exploitation, putting in place infrastructure to deliver genomic services and selection
Threats due to climate change, environmental hazards and natural disasters	Educate farmers on production practices that address the effects of climate change, engage farmers in the active preparation and readiness to address environmental hazards and natural disasters that may happen at any time
Limited human capacity for sustainable livestock production practices that support livestock improvement	Continually increase the knowledge base/capacity of farmers and other stakeholders (policymakers, extension workers, veterinarians, students and associated animal production professionals) in animal production and improvement practices
Lack of active farmer groups and breed associations and no linkages across livestock production groups and between universities and research organisations	Building of effective farmer groups and breed associations to harness resources, knowledge sharing for decision-making when needed, government funding to support the establishment of farmer groups and breed associations, and active interactions between farmers, universities and research organizations

(continued)

Table 2.5 (continued)

Challenge	Possible intervention
Limited adoption of improved reproduction and breeding practices	Educate and encourage farmers to adopt improved reproduction and breeding strategies, for example, encouragement of the use of artificial insemination, even in smallholder systems; development and implementation of appropriate selection programmes adapted to each production system; improvement of the provision and affordability of innovative technologies such as artificial insemination, incubation services and genomic selection services

through generations. Therefore, there has been little or no motivation for innovation, nor investment or business plans to help improve the traditional systems. There is little or no monitoring of animal performance, and therefore, there is little data available on which the selection for improvement can be based. Moreover, indiscriminate cross-breeding and poor genotype–environment matching make it difficult to achieve maximum benefits from most breed improvement programmes.

Smallholder farmers are accustomed to expecting aid from governments, policymakers, researchers and international partners to address the issues of low feed quality, limited availability of feed resources and the tackling of animal diseases. However, the practices and attitudes of farmers must change as active solutions must start with them. Adequate feed resources and feed security and disease management are the foundations to the sustainable improvement of animal productivity. Drawing on endogenous knowledge and disease management practices as well as promoting systems that are ecologically sustainable is part of the solution. Integrating crop–livestock production, as seen within the smallholder mixed crop–livestock production system, has been described as a viable agro-ecological system approach that can support feed availability/reduction of feed shortage as well as an effective approach to the management of rangelands (Lenné and Thomas 2006). The mixed crop–livestock production system is commonly practised in West Africa, and more attention from research can find the best synergy between crops/forage crops and animal feeding to make this production system sustainable. In the Republic of Benin, for example, a relationship exists between crop and cattle production in agro-pastoral areas at the household level, whereby cattle herders exploit crop residues from crop farmers after the harvest in exchange for manure (Djenontin et al. 2002). The manure from cattle supplies nutrients to the soil, thereby increasing soil fertility to support healthy plant growth and rangeland health. In Cameroon, the various pastoralist initiatives for rangeland and water resource management include the effective distribution of grazing areas, grazing land management, reorganisation of herd mobility and combination with other adaptive management practices (Moritz 2012). To strengthen the adoption of integrated crop–livestock systems, Sekaran et al. (2021) suggested that government polices need to support capital investments, infrastructure and on-field demonstrations, particularly for small and marginal farmers, and provide greater attention to include small ruminants, protein-rich crops, fruits and vegetables in the system.

2.4.2 Feed Resources' Availability and Quality

Feed availability and quality impact livestock productivity, profitability, environment, nutrition security for humans and animals, animal welfare and ethics and health (animal and human). In semi-intensive-to-intensive systems, feed costs accounts for 70% or more of the total variable costs of production, implying that good-quality

feed is an important component of such systems. Proper feeding of high-quality feedstuffs directly translates to improved animal productivity, health, welfare and reproductive performance; increases productive life and profitability and enables higher productivity under a given management regimen and environmental sustainability.

Limited availability and access to quality feed materials continue to be the most important limitations to livestock production in Africa. Inadequate availability and supply of quality feed and water critically limit the efficiency of livestock in terms of production, reproduction, health and welfare and the economic benefits derived from livestock-based products. The mainly extensive and smallholder livestock production systems are shaped by the agro-ecological zones, and the amount of rainfall is a main determinant of the availability and quality of forage for the nutrition of majority of livestock produced on the continent. With increasing drought conditions due to changing climates, feed and water resources are dwindling in amount and quality, calling for tailored interventions. Countries in East Africa identified, a lack of animal feed policy, strategy and institutional framework to support the animal feed sector, as a major constraint hindering subsector growth, livestock productivity, resilience and trade (Opio et al. 2020). The implementation of a regional livestock feed action plan will enhance the efficiency of utilisation of natural resources, opening new avenues for the development of a sustainable bioeconomy in East Africa. Climate change/variability is an important issue in the semi-arid and arid regions of Africa, especially in pastoralists' and agro-pastoralist's food and nutrition security and livelihood outcomes (Opio et al. 2020). A range of actions for sustainable feed production was recently proposed (Balehegn et al. 2020) and includes (i) improving feed productivity by improving biomass production and availability; (ii) enhancing feed quality by focusing on improving nutritional value, palatability, intake and digestibility of low-quality feeds; (iii) maintaining/preserving feed quality by preserving the nutritional quality of feeds during storage for off-season feeding; (iv) enhancing the nutritional status of animals through the supplementation of diets with high-quality nutritious ingredients that supply critical nutrients, and enhancing the digestion and assimilation of feed; and (v) using high-quality analytical and operational technologies to improve feed quality analysis, quality control, marketing, packaging, transportation and feeding.

Generally, informed strategies for the improvement of feed resources, both qualitative and quantitative, tailored to suit the needs of the different livestock species and production systems are prerequisites for sustainable livestock productivity in Africa. For example, access to improved communal rotational grazing pastures and fodder banks, which should be regularly maintained to ensure the quality of feed resources, will enhance sustained livestock production in these systems (Ibeagha-Awemu et al. 2019). Moreover, legislations instituting the development of watersheds, restrictions on indiscriminate burning of grazing land and their use for other purposes, increase grain production for livestock feeding, development of improved pastures and fodders, development of agricultural by-products as feed resources and access to water resources, and feed markets will support a durable livestock sector (Ibeagha-Awemu et al. 2019).

2.4.3 Climate Change

African livestock production systems operate under a wide range of environmental conditions and are increasingly affected by climate change. Global warming and its associated changes in mean climate variables and climate variability affect feed and water resources as well as animal health and production. Climate change also has implications for the processing, storage, transport, retailing and consumption of livestock products. The ability of current livestock systems to support livelihoods and meet the increasing demand for livestock products is thus threatened. Climate change may also impact infectious livestock diseases by changing their spatial distributions, affecting annual and seasonal cycles,

altering disease incidence and severity and aiding the susceptibility of livestock to illness. Furthermore, climate change is expected to directly depress animal adaptive response mechanisms, cause heat stress and related welfare issues and compromise the availability of feed crops and quality of forages. For example, most indigenous cattle owned by smallholder farmers are raised entirely on communal rangelands. Communal rangeland productivity is affected by climate change and degradation caused by uncontrolled grazing, encroachment of indigenous woody plants and the spread of invasive alien plants. Therefore, it is important to develop and implement innovative community-based rangeland management and forage conservation technologies (Marshall 2014).

Projected increases in extreme weather events and changes in feed availability, composition and quality of animal diets will affect the availability of animal products and food supply due to increasing human population growth and demand for livestock products. Some of the negative consequences of climate change for ruminant livestock production can be mitigated through the use of adaptive management and breeding approaches. Examples include the use of energy-efficient cooling systems for animals, proper nutrition, water availability and access, use of heat-tolerant (thermotolerant) breeds and genetic selection to improve the production, fertility, health and survival under heat stress conditions (Henry et al. 2018).

2.4.4 Disease Burden

Disease burden and limited access to drugs and veterinary care are major limitations for livestock production in Africa. For example, smallholder pig production in Uganda, like in most countries in SSA, is constrained by poor management and high disease burden, with African swine fever being one of the most important perennial threats responsible for decimating Africa's pig genetic resources. Under poor management and husbandry practices, there is an increased risk of transmission of highly infectious diseases, including African swine fever (Escarcha et al. 2018; Dione et al. 2017). Biosecurity measures are not followed in the majority of livestock enterprises, which calls for the need to raise awareness among farmers about the dangers of disease outbreaks to the farm and society. Given the high cost of imported drugs, the improvement of traditional livestock disease control methods and exploitation requires revisiting and harnessing traditional disease control methods, which in conjunction with improved animal housing, feeding management, and breeding for disease resistance are sustainable solutions to support sustainable animal production and product quality.

Furthermore, the use of antimicrobial products to promote growth and prevent disease in healthy food-producing animals has exacerbated the emergence and spread of resistant microorganisms. Consequently, the sector can only deliver on expectations if, among other measures, the productivity and income of small-scale food producers are improved, sustainable and resilient food systems are promoted, the diversity of genetic resources is maintained, the proper functioning of food markets is ensured, and the use of antimicrobials is reduced through better access to quality veterinary services and good animal husbandry practices (FAO 2018d).

2.4.5 Limited Access to Innovative Technologies

Livestock production systems in Africa are often challenged in many ways regarding the infusion of innovative technologies for improved efficiency. For example, dairy farming is an important source of income and nutrition for many smallholder farmers in East Africa (Mwanga et al. 2019). However, the most challenging critical factors hampering the success of oestrus synchronisation and mass artificial insemination service delivery in dairy cows for smallholders in Ethiopia are the improper selection of cows/heifers, small and scattered herds rendering impossible the insemination of a large number of cows/heifers in 1 day and at a specific place, the

absence of a data-recording system, the lack of clearly defined share of responsibilities among stakeholders, poor communication and collaboration among stakeholders, the lack of motivation and skills of artificial insemination technicians, the lack of support and limited availability of inputs, feed shortages, poor heat detection and wrong insemination time by smallholders and lower reproductive performances of both indigenous and crossbred cows, which consequently contribute to limited success of the technologies (Abebe et al. 2021). Genetic diversity losses are often aggravated by focusing on specialised exotic breeds and crossbreds, and production systems, the failure to evaluate indigenous breeds and inappropriate breed replacement, especially in post-disaster rehabilitation programmes that involveg the introduction of breeds that are not adapted to local production environments (Mapiye et al. 2019).

2.4.6 Lack of Clear Breeding Goals and Genetically Improved Livestock

Intentional breeding and selection through setting and implementing clear breeding goals are prerequisites for sustainable animal breed improvement. Unfortunately, this has generally not been the case in the African livestock sector, where breeding is mostly random, and coupled with poor feeding and management practices, livestock productivity is low. When compared with Western breeds, which are under sustained breed improvement programmes and improved management practices, African livestock are erroneously tagged 'unproductive'. To make the transition from 'unproductive' to 'productive', African indigenous livestock too must be intentionally selected and placed under improved management practices. An intentional selection programme will start by setting clear breeding goals and the selection of best-performing individuals for the traits under selection as parents of the next generation, coupled with improved management practices. Taking advantage of improved technologies, like the implementation of genomic selection, will lead to rapid progress in desired traits. Repeated circles of such intentional actions will lead to the development of genetically improved individuals for the traits under selection. Setting the breeding goals to meet today's challenges for sustainable animal breeding should consider the following: (i) market-oriented and non-market-oriented value traits, (ii) the specific needs of farmers, (iii) social and religious needs, and (iv) ecological and environmental adaptation goals (Ibeagha-Awemu et al. 2019). The breeding goals, which must be tailored to fit the conditions of each production system, must be supported by appropriate education, the involvement and cooperation of stakeholders and appropriate government policies and financial input. The setting of appropriate breeding goals of African livestock genetic improvement are discussed in Chapters 15, 16, 17, 18 and 19.

Generally, matching genetics to the production environment is a major challenge. Recording and selective breeding can serve as means of ensuring the identification and/or development of genotypes that fit in current and evolving production environments. Cross-breeding and/or upgrading of African indigenous livestock with exotic breeds have been the commonly rushed strategies implemented to improve the genetics of African livestock for increased productivity. Such introduced genetics, which have been developed over long periods in different environments, do experience genotype by environment interactions, which markedly lower performance after the F1 generation in the African environment where they are introduced. It has been observed that the adoption of 'shortcut approaches' or 'rushed strategies' of utilising exotic genes to improve African livestock has generally not resulted in substantial gains nor sustainable long-term increases in productivity or contributed to poverty alleviation (Ibeagha-Awemu et al. 2019). Moreover, cross-breeding programmes between exotic and indigenous breeds were intended to improve biological and economic efficiency, but their unstructured nature has produced nondescript crossbred individuals, e.g. crossbred cattle that are currently dominant in most smallholder livestock production systems

in East Africa, resulting in the erosion of genetic diversity. Careful selection programmes and conservation of indigenous cattle breeds are critical for reversing the unprecedented loss of diversity and ensuring the security of cattle genetic resources for economic, ecological and social benefits for the short and long terms. To improve production through crossing with exotic breeds, careful selection objectives and judicious implementation of cross-breeding with improved indigenous breeds for desired traits in combination with relevant biotechnologies and improved management practices may support the sustainable improvement and use of African indigenous livestock genetic resources. Key strategies to maintain diversity and ensure the sustainable use of indigenous African AnGR should include sustained genetic improvement programmes targeting unique productive and adaptive traits; improved nutrition, healthcare and housing; appropriate infrastructure; integration and empowerment of women and youth; and institution of appropriate marketing channels, capacity building and regulatory and policy frameworks (Mapiye et al. 2019).

2.4.7 Lack of Necessary Infrastructure and Inputs

Access to infrastructure for the general development of livestock production within the African continent is limited, including access to basic equipment for data, storage and traceability, computing infrastructure to deliver genomics services/information, animal housing, pasture development, animal handling and transport, livestock markets, slaughter facilities and health and nutrition management, among others. High cost/limited access to inputs such as veterinary drugs, fertilisers and soil nutrients, among others, are additional factors limiting livestock development in Africa. Making available these infrastructures will support rapid development of the African livestock sector.

2.4.8 Lack of Enabling Government Policies in the Livestock Industry

Successful and sustainable development of the livestock industry in any given country or region depends on the development of clear national, regional and continental policies as well as guiding principles in the conduct of affairs (Ibeagha-Awemu et al. 2019). However, this is not the case in most African countries, which lack clear supply and demand policies that favour local production nor recognise the positive impact of livestock in the livelihood of smallholder farm families and the nutrition and economy of individual countries. Where some sort of policies exist, there is a general lack of political commitment to implement national, regional and continental livestock policies, which are keys to stimulating, developing and financially sustaining the livestock value chain development.

Therefore, the development of enabling livestock policies at all levels of governance (national, regional and continental) is key to realising the full impact of the livestock sector on the continent, and the factors that should be considered for putting in place enabling policies include (1) understanding of the characteristics and challenges of current livestock production systems; (2) broad consultation with all stakeholders (e.g. farmers, consumers, policy makers, professionals, service providers, marketers, etc.); (3) demonstration of the will to address concerns and needs through policy; (4) creation of policy and institutional environments suitable for mainstream livestock farming systems; (5) creation of policies with appropriate incentives for farmers and agribusiness to encourage the implementation of livestock development strategies at all levels; (6) creation of policies that allow access to markets, information, healthcare, nutrition and other agricultural services as these are the backbone to decreasing productivity gaps and ensuring sustainable livestock improvement, food security and improved livelihoods; (7) creation of

policies that support increased investments in technological innovations and research such as incorporating transdisciplinary strategies with focus on reducing productivity gaps in all production systems and promotion of novel and effective production systems and uptake of innovative technologies; (8) creation of inclusive policies that develops and strengthens human (paying attention to gender equity) and social capital in suitable ways for each livestock production system; (9) creation of policies to ensure access to grazing lands, cultivated lands and water resources and develop improved pastures and restore degraded lands; (10) creation of policies that support sustainable intensification and diversification within the various production systems with appropriate climate-smart practices to improve livestock productivity in the face of increasing climatic variability and market volatility; and (11) creation of policies that stimulate local production and encourage inter-country and international trade in livestock products. Finally, setting national, regional and continent-wide policies and strategies must be accompanied by the development and implementation of livestock breeding laws that address the technical aspects of animal genetic resource management and harness factors like institutional arrangements, roles and responsibilities of various bodies and decision-making process that influence the implementation of legislation and policies. The policies, frameworks, strategies, and action plans for advancing the African livestock sector are presented in Chapter 30 and the resourcing institutional arrangements are discussed in Chapter 31.

2.5 Future Trends and Drivers of Transformation of African Livestock Production Systems

In general, past livestock production systems in Africa were mostly subsistence smallholder enterprises with the main production objective of satisfying household and/or family needs with little commercial motives. The main animal resources were indigenous breeds, often passed down the family line. In addition, animal farming was part of crop production, with farmers and governments making little investment in housing, feeding, veterinary care and new genetics. However, with the increasing demand for animal protein due to population growth, most farmers are beginning to adopt innovative technologies and improved practices to increase the productivity of their stock.

Present-day livestock production systems in Africa are diverse and dynamic and include (1) those where existing indigenous breeds are currently optimal and likely to remain so, (2) those where non-indigenous breed types are already in common use and (3) systems that are changing by intensification, where the introduction of new breed types represents significant opportunities. These systems will continue to evolve in response to many factors including but not limited to human population growth, increasing demand for livestock products, shift in natural resource availability, climate change, scientific innovation and technological advances, human capacity development and gender equity, livestock business, markets and marketing channels and supporting institutional structures and enabling policies (Fig. 2.9). These drivers present opportunities to support rapid improvements in sustainable livestock production and, consequently, enhance the livelihood of Africans through increased food and nutrition security and environmental sustainability.

2.5.1 Human Population Growth and the Demand for Livestock Products

Increasing global human population growth projected to reach 9.7 billion by 2050 (UN 2022) and increasing incomes and purchasing power will continue to push up the demand for animal proteins and livestock-related products. With more and more people choosing to live in urban areas, it is projected that more than two-thirds of the world population and 60% of Africans will live in urban areas by 2050. Urban dwellers are known

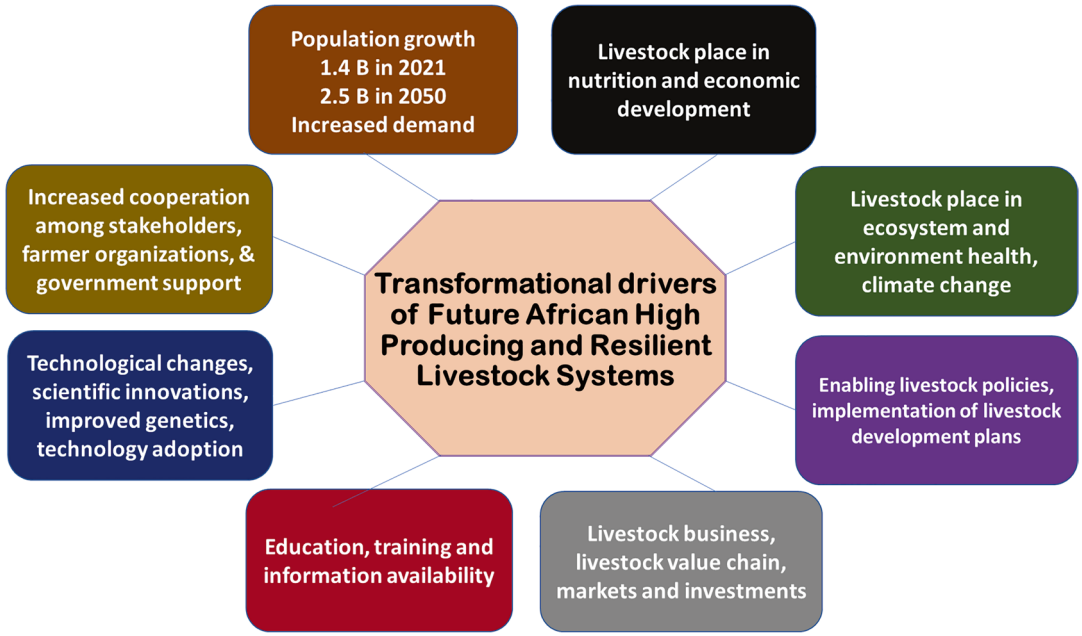

Fig. 2.9 Transformational drivers of current and future African high-producing and resilient livestock production systems

to embrace new habits, including increased consumption of animal-sourced proteins. A recent study estimated that the demand for meat and milk by African urban dwellers may triple by 2050 (Latino et al. 2020). The current growth of peri-urban intensive livestock operations and the growth of intensively managed large poultry and pig farms have been largely driven by the increased demand for animal products by urban dwellers. The current and projected increased demand for animal-sourced foods will only intensify and will add to the existing pressure on ecosystems and biodiversity, and livestock producers will face greater competition for capital, labour, land, water and energy.

In Tanzania, for example, a relatively small number of livestock keepers have adopted exclusively commercial production to meet the growing demand for livestock products by urban populations (de Glanville et al. 2020). Moreover, the commercialisation and intensification of livestock production is strongly promoted by the Tanzanian Government through beef ranching and the establishment of zero-grazing dairy units to support exotic breeds of cattle. In recent times, Maasai pastoralists are increasingly adopting crop production as a response to changing land tenure practices in northern Tanzania. Widespread adoption and subsequent change within traditional pastoral systems could conceivably lead to it becoming broadly indistinguishable (in terms of production) from neighbouring agro-pastoral systems (de Glanville et al. 2020). The ranching system, if popularised and successfully implemented, could help overcome some of the challenges associated with the large-scale extensive pastoral and transhumance systems and lead to improved productivity.

These factors are real opportunities that are set to push the livestock industry towards larger, intensively managed operations, resulting in higher outputs to satisfy the demand. Hence, the increasing demand for livestock products may drive the reformation of existing livestock production systems towards more effective and productive systems.

On the other hand, Bonnet et al. (2020) report that the increased demand and consumption of meat in developed countries may increase the risk of some chronic health diseases, and in par-

ticular, increased ruminant production is a significant source of greenhouse gas (GHG) emissions and a major driver of deforestation and worldwide biodiversity loss. Other limitations associated with increased livestock production include environmental pollution (water, soil and air), development of antibiotic resistance, increased incidence of zoonotic diseases, emergence of new disease pathogens and increased animal welfare issues. These potential negative impacts must be considered when developing strategies for increased livestock productivity to satisfy the increasing demand.

2.5.2 Technological Changes and Adoption

Technological advances have been the major drivers of improved livestock productivity, and their massive roles in advancing livestock productivity will only increase. Technological advances in reproduction (e.g. artificial insemination), breeding (e.g. genomic breeding) and feeding (precision feeding) technologies, etc., have left their marks on advancing livestock productivity. Today, these technologies and other emerging technologies (see Chapters 20 and 21) are advancing at a faster pace, and their adoption, including technologies to capture and manage big data, are poised to address the challenges facing low livestock productivity in Africa towards a more productive and rewarding livestock sector. For example, the widespread use of artificial insemination, multiple ovulation and embryo transfer reproductive methods; more efficient statistical tools for genetic merit estimation; the use of molecular genetics and DNA-based methods to study animal genomes for genomic selection to increase the rate of genetic gains for most traits and health management and the possibilities presented by cloning and transgenic livestock production, as well as the possibilities presented by future technologies (Ibeagha-Awemu et al. 2019) are modern tools whose adoption can promote rapid growth of the African livestock sector. In a recent empirical study, smallholder livestock farmers in SSA indicated that the use of digital technologies could enhance their risk mitigation and value chains, which supports the overwhelming need for the use of emerging technologies by smallholder livestock farmers in SSA (Gwaka and Dubihlela 2020). New technologies such as mobile telephones, new strategies and tools for livestock health management and changes in land tenure and land availability may also lead to change within traditionally defined production systems. Therefore, national governments need to invest in these emerging technologies and put in place the appropriate infrastructure to encourage stakeholders to embrace these technologies across Africa.

2.5.3 Education, Training and Information Availability

Africa is home to many higher institutions providing education and training on different aspects of livestock production, transformation and marketing (See Chapters 27 and 28). Although not currently operating at optimal capacity, these institutions have opportunities through inter-country, inter-regional, continent-wide and international collaborations to build capacity and contribute positively towards revamping the livestock sector and realising its full potential. Many international organisations, such as the International Livestock Research Institute (ILRI) and non-governmental and professional organisations on the continent engage in student and farmer training on aspects of livestock production, management and trade. Moreover, open-access availability of scientific information, a concept promoted by many countries and facilitated by technology (e.g. Internet accessibility), means that the knowledge necessary to revamp the African livestock sector is freely available and that harnessing it will result in the rapid growth of the livestock sector. It was stated recently that better collaboration between institutions of higher learning such as universities, research organisations (national, regional, continent-wide and international), farmer groups, non-governmental organisations and national governments is the key to ensuring the flow and

sharing of information and knowledge (Ibeagha-Awemu et al. 2019).

2.5.4 Livestock Business, Markets and Investments

Recognition of the livestock sector and its promotion as a viable driver of national economies will garner interest in livestock production as a viable income-generating venture. This requires appropriate government incentives and investment to build a sustainable livestock sector. Most importantly, every livestock enterprise should be market-oriented, and marketing channels should be made available to facilitate trade in livestock products. Also, trade in livestock and livestock products in most African countries is performed through informal channels requiring much effort, and adequate measures need to be put in place for the acquisition of the true livestock marketing statistics within and between African countries.

In recent years, efforts are being made by national governments and regional and continental bodies to promote trade in livestock. For example, the Ethiopian government's strategy of encouraging foreign trade of sheep and goat products has seen the creation of employment opportunities for many of its citizens (Nwogwugwu et al. 2018) as well as the emergence of livestock feed and poultry businesses in West Africa (Konlan et al. 2018). Also, the growing inter-regional trade in livestock between the member states of the Economic Community of West African States (ECOWAS) and the Economic Community of Central African States (ECCAS) and among Southern African Development Community (SADC) and East African Community (EAC), plus Libya and Egypt (Valerio 2020), will continue to grow due to increasing population growth, which will stimulate increased productivity. Moreover, the full implementation of the African Continental Free Trade Area (AfCFTA), which seeks to ease free trade barriers between member states, may help formalise Africa's large informal livestock trade sector and increase trade in livestock products between states and also internationally. Greater involvement of the private sector will drive livestock extension services and stimulate the growth of the sector. Therefore, the increasing African urban demand as well as the global demand for livestock products are potential drivers that can transform Africa's livestock value chains and international trade in livestock products.

2.5.5 Enabling Livestock Policies

Recent time has seen the emergence of various livestock-oriented policies by national governments and regional bodies and continental policies with the goal to achieving rapid growth of the livestock sector.

The AU-IBAR (https://www.au-ibar.org/) has, since its inception in 1951, implemented a mandate to support and coordinate the improved and sustainable utilisation of livestock, fish and wildlife species as viable resources for the sustenance and well-being of Africans. Its main mission of ensuring that animal genetic resources contribute substantially to the reduction of poverty and hunger in Africa has been/is being realised through the implementation of various past, ongoing and future projects. The African Union LiDESA for Africa (2015–2035), developed through an inclusive consultation process involving stakeholders and experts at national, regional and continental levels (AU-IBAR 2015), recognises the central role played by livestock in the lives of Africans. The LiDESA 2015–2035 aims to transform African livestock productivity for accelerated, sustainable and equitable growth and for increased contribution to socio-economic development (see Chapter 30). These goals are in line with ongoing strategies, policy frameworks and guidelines in place in many African countries as well as mirror the frameworks and agenda in individual countries, regional economic communities and throughout the continent. Moreover, livestock are central to achieving all 17 current UN SDGs (FAO 2015), and the careful implementation of these goals in Africa will contribute to sustainable livestock productivity and raising livelihoods. These policy frameworks are, therefore, positive steps towards the sustainable utili-

sation of African animal genetic resources and present opportunities to stimulate increased livestock productivity.

2.5.6 Livestock's Place in Ecosystem and Environment Health

While the livestock sector is critically important to Africa as it performs vital nutrition and development functions through its contribution to dietary needs, economic growth and environment health, it is also responsible for about 70% of agricultural GHG emissions, overgrazing and associated wide-ranging land degradation and loss of biodiversity. To curb livestock production's negative impacts and ensure sustainability in food systems and the positive role of livestock, a whole system approach to livestock production, climate-smart interventions, carbon-neutral production systems, proper grazing and rangeland management, improved forage-based systems, preservation of natural systems, proper manure management, improved housing, improved animal health management and genetics are increasingly being adopted by many countries.

It is recognised that about 90% of ruminants on the African continent are raised on grazing lands (Robinson et al. 2011), which also support about 30% of global domestic ruminant production and 30% of animal-sourced proteins (Mottet et al. 2018). Globally, about 1.5 billion hectares of land not suitable for growing crops due to poor soil fertility, rainfall and topography are exploited for livestock grazing system (LGS), as well as 54% of total terrestrial landscape (Ickowicz et al. 2022). Most of the unsuitable lands (about 28 M km^2) are found in desert or marginal shrubland areas (ILRI et al. 2021). Many LGSs are characterised by the mobility of livestock and people, as seen in most pastoral systems, and the reliance on natural resources and processes such as native pasture, water source, manure and high human capital input. A global analysis of the land footprint of LGSs, their associated management of livestock and their impacts on the ecosystem dynamics using a multifunctional conceptual model and a holistic approach (production and social, environmental and local development) demonstrated the potential contribution that LGSs may bring to sustainable food systems (Ickowicz et al. 2022). Case studies of LGS impact are summarised in Box 2.2.

Climate-smart livestock strategies and interventions can enhance the productivity of livestock, particularly under low-input or resource-restricted systems, with positive impacts on climate change adaptation, mitigation and environmental resilience (Gaitán et al. 2016). Moreover, climate-smart interventions in various components of the livestock production practice can decrease GHG emissions and the intensities of emissions and increase carbon sequestration, with the consequence of contributing to a system-wide negative carbon balance (Ortiz-Gonzalo et al. 2017).

Agro-forestry systems, generally regarded as carbon-neutral production systems, such as silvopastoral systems, can contribute to reductions in GHG emissions from livestock through the contribution to carbon sequestration and improved feed quality (Feliciano et al. 2018).

Proper grazing and rangeland management can increase biomass production and biodiversity, and well-managed grasslands can store up to 260 tonnes of carbon per ha (Savory and Butterfield 2007; Gebregergs et al. 2019). Moreover, interventions like zero-, moderate- and rotational-grazing can enhance carbon sequestration by grazing lands and increase livestock productivity (Gebregergs et al. 2019). Improved forage-based systems promote increased herbage biomass and livestock productivity (Paul et al. 2020). Integration of forage technologies with food crops was shown to reduce soil loss by ~50% and increase soil organic carbon by 10%, stover yield by 33% and grain yield by 60% (Paul et al. 2020).

Box 2.2 Summary of case studies on the impact of livestock grazing system (LGS) management using a multifunctional approach (Ickowicz et al. 2022)

***Case study 1*: Argentina: The Puna high-altitude, dry pastoralism**

Social indicators: Household members and the number of local organisations in the supply chain.

Environmental indicators: Plant cover, dry matter production and biodiversity.

Production indicators: Meat sold in kilograms, diversity of livestock and drought management strategies.

Local development indicators: Yearly income and number and diversity of marketing channels.

Impact/results: The approaches for resilience centred on social networks and the diversity of livestock species associated with the local supply chain and household members linked to wealth generation. The system of grazing maintains vegetation condition and diversity, with plant cover regulating soil temperature and water.

***Case study 2*: Senegal: Ferlo Rangeland–based dairy milk platform**

Social indicators: Collaboration between forage producers and social inclusion.

Environmental indicators: GHG emissions and biomass production.

Production indicators: Efficiency of milk collection, milk production (litres/day) and biomass flows.

Local development indicators: Biomass supply network, income from milk and milk value chain development

Impact/results: Evaluation of three scenarios of dairy intensification identified the trade-offs between inputs and outputs and the environmental and social consequences and assisted in the development of the sector strategy.

***Case study 3*: Brazil: Maranhao silvo-pastoral systems**

Social indicators: Profit and employment.

Environmental indicators: Carbon balance, animal welfare and biodiversity.

Production indicators: Amount of meat (kg)/ha/year

Local development indicators: The number of associated businesses

Impact/results: Achieved higher profit compared with monoculture, with potential for further gains through payments from additional ecosystem services provided, increased flora and fauna biodiversity, enhanced animal welfare and enhanced soil conservation.

***Case study 4*: Mongolia: Bulgan forest steppes conservation coexisting with livestock systems**

Social indicators: Participating farm families, household income and diverse employment.

Environmental indicators: Increase in the numbers of existing species and reintroduction of species.

Production indicators: Livestock production.

Local development indicators: New business prospects.

Impact/results: The positive uptake by herder households of conservation-related employment positively alleviated poverty and improved environmental outcomes without affecting existing livestock systems.

Therefore, the implementation of sustainable livestock production systems is key to increasing livestock productivity in Africa.

2.5.7 Adapting Livestock Systems to Mitigate Climate Change Effects

The potential impacts of climate change on current livestock systems worldwide and in Africa, in particular, are a major concern. The consequences of climate change include the production of GHGs such as methane and nitrous oxide. Methane is mostly generated by ruminants during enteric fermentation (a biological process for removing carbon dioxide and hydrogen from the rumen to maintain fermentation) or the anaerobic decomposition of excreted manure. In livestock, high-concentrate-diet-fed livestock are known to produce faecal and urine output rich in nutrients, which leads to environmental pollution. This indicates poor nutrient use efficiency of nitrogen and phosphorus in the agricultural production system. Despite the related adverse environmental effects, agricultural production practices are the primary routes to achieving food security and ending world hunger by improving protein and other nutrient needs in human diets. Nutritional strategies (e.g. feed supplementation) and manure processing (e.g. anaerobic digestion (biogas)) can be used to reduce GHG emissions and recycle nutrients, thereby increasing the nutrient use efficiency of animals. Mostly, the ruminants in Africa are raised for meat production, which is often associated with low feed efficiency and high GHG emission intensity (Herrero et al. 2013) due to slow growth rates. Reducing emissions without lessening the ruminant population requires either good-quality feed supplementation or improved yield. Genetic improvement of indigenous livestock for disease- and heat-tolerant traits will be useful in this regard. Adaptation of livestock to heat stress is an essential practice in sustainable livestock farming because of the higher methane produced from heat-stress-susceptible animals (Hyder et al. 2017). The adaptation to marginal lands and the potential for lower emission intensity could favour small ruminant rearing in Africa.

Therefore, climate-smart agricultural (CSA) practices will ensure the sustainability of Africa's livestock production systems. The CSA practices focuses on three major pillars: (1) sustainable increase in productivity to support the development and equitable increase in farm incomes and food security, (2) increased resilience and (3) reduction or elimination of GHG emissions (mitigation) (Chandra et al. 2018). The CSA practice is a relevant mechanism to support food system transformation in Africa as its role in GHG mitigation is as important as food security and climate change adaptation (Anuga et al. 2020).

2.5.8 Livestock's Role in Responses, Recovery and Rebuilding Measures Against Pandemics

Pandemics and other natural disasters can have profound impacts on nurturing livelihoods and global food security, including livestock production and its sustainability. Evidence from the recent COVID-19 pandemic and past pandemics indicates disruptions to the livestock value chains with dire socio-economic impacts on production, processing and transport (FAO 2020c) (Obese et al. 2021), including reduced access to animal feeds, reduced inputs and services, reduced market access, reduced processing capacity (e.g. meat and dairy processing industries), compromised storage and conservation, constrained informal businesses (e.g. dairy and meat trading in developing countries is mostly informal), constrained national transport (e.g. movement restrictions and transport disruptions), international trade restrictions, modified retailing methods (e.g. online) and reduced consumer purchasing power, demand and public procurement.

To ensure the sustainability of the livestock value chains during pandemics, the FAO proposed the implementation of the actions listed below (FAO 2020c):

1. Tailor measures to protect animal production and markets: Such measures may include (i) the establishment of production safety nets such as new or resupplied feed reserves; (ii) the issuance of special driving permits to allow animal feed distribution in remote areas during pandemics as well as putting in place waivers for agri-food system operations to keep inputs flowing; (iii) empowerment of producer organisations to advance bargaining through collective purchasing and marketing; (iv) active coordination of the supply of inputs for livestock production; (v) promotion and/or funding of the local sourcing and production of feed and supplements for animals; (vi) launch of emergency management procedures and services to provide timely communication to control rumours, guide stakeholders, get feedback and move staff and resources to tackle crisis relief activities such as health management and food inspection; (vii) permission for food markets to stay open and manage physical distancing through public health-conscious rules, procedures, materials and equipment and through the protection of environments (water, land, biodiversity and ecosystems) where diseases are common; and (viii) keeping open borders (within and between countries) for imports and exports of relevance to all areas of the value chain, permission for transboundary livestock movement and allowing for access to essential natural resources for pastoralists.
2. Put in place measures to support processing and retail operations: Such measures may include (i) providing clear guidelines for pandemic control, management and prevention along the supply chains to protect all value chain participants and their families; some of the provisions could be for increased biosecurity, personal hygiene and protective equipment; (ii) increasing funding to support packaging and freezing capacities as well as encouraging enterprises (small and medium) to engage in the production of safe products and those with long shelf lives; (iii) putting in place group slaughterhouses or points and supporting the installation and use of cold chain to reduce slaughtering frequency and improve meat inspection; (iv) ensuring that children participating in school feeding programmes are reached as well as distributing foods rich in animal proteins to enhance nutrition and incomes of smallholder families; and (v) promoting timely collection and distribution of milk to processing companies.
3. Ensure adequate financial measures: Such measures may include (i) funding milk collection centres and factories to enhance the purchasing power for milk supply and processing of products with long shelf lives; (ii) supporting businesses (small- and medium-sized) in the short-term relief of pandemic impacts through temporary tax relief programmes, tax exemptions, emergency loan programmes, direct stimulus payments, loan repayment extensions, grace periods to repay loans, lower interest rates and public investments and subsidies; (iii) putting in place mentoring and training programmes to support enterprises (small- and medium-sized) in assessing and managing the financial impact of pandemics, going digital and finding new markets; and (iv) making available subsidies to agri-food sectors to help them continue activities during lockdown as well as implementing price controls to reduce the effect of inflation on livestock commodities.

2.6 Conclusion and Perspective

African livestock production systems are diverse, dominated by small-scale subsistence livestock farming, and depend largely on rain-fed agriculture. More in-depth characterisation of the existing production systems is, however, needed for informed decisions on their improvement. Current livestock productivity levels are not enough to satisfy the growing consumer demands for livestock products and will continue to remain so if present challenges are not mitigated. Stimulating factors outlined in Section 2.5, like population growth, availability of knowledge and technology and the willingness by national and international bodies to support livestock produc-

tion, present real opportunities for the rapid evolution of African livestock production value chains of the future. By consideration of the aforementioned stimulating factors, many new livestock production typologies could emerge from demographic challenged, low technical know-how, technology poor, policy starved and environmental change threats, towards more resilient, productive and environmentally friendly livestock production systems. Additionally, national governments and stakeholders by ensuring that appropriate capacity building, land use and animal resource conservation policies backed by appropriate legal and regulatory frameworks are implemented will not only safeguard the rich and unique livestock production systems in Africa but also ensure that its almost 1.5 billion inhabitants derive maximum benefits from them.

3 The History, Geography, and Characteristics of Indigenous African Taurine Cattle

John E. O. Rege, Chi L. Tawah, Isidore Houaga, and Eveline M. Ibeagha-Awemu

Abstract

This chapter introduces indigenous African cattle—their origins, the history of their introduction, and subsequent dispersal across the continent. The first two sections (Sect. 3.1 on origins and history and Sect. 3.2 on present-day breeds and strains) provide a broad coverage of all African cattle, using a framework that can help trace the roots of the different breeds of African cattle that exist today. Sections 3.3, 3.4, and 3.5 are then dedicated to the African taurine cattle, the cattle considered to have originated and evolved in Africa, consisting of two major groups—the Taurine Longhorns and the Taurine Shorthorns. For each breed or strain within each of these groups, the chapter summarizes the classification; distribution; ecological settings; physical, adaptive, and special genetic characteristics, including selected breed photos; predominant production systems; and production characteristics. Some breeds and strains are similar in various dimensions of the coverage and are thus covered in groups. Moreover, the differential availability of data/information led to the difference in the depth of coverage between breeds and strains. The chapter concludes by presenting a summary of the risk status of the taurine breeds of Africa, especially noting the increasing interbreeding among neighbouring breeds, as well as intentional cross-breeding, and making a case for conservation actions for those at risk of extinction. The chapter also advocates for characterization efforts to enhance understanding of these breeds to inform programmes for their sustainable use. Section 3.5 presents a summary and conclusion.

3.1 Origins and History

Archaeologists and biologists agree that there is strong evidence for two distinct domestication events from aurochs: *Bos taurus* in the Near East about 10,500 years ago, and *Bos indicus* in the Indus valley of the Indian subcontinent about 7000 years ago. Archaeological findings, however, have led to the new theory that there was an African centre of domestication in the Sahara from southern Libya and north-western Niger to southern Egypt (MacDonald and Hutton MacDonald 2000) and that this third domestication in Africa (of a domesticate, which has been referred to as *Bos africanus*) happened about 8500 years ago. Further genetic studies have also suggested that the present-day humpless cattle populations are so divergent from similar cattle populations of Europe that separate domestication could, indeed, have occurred in Africa (Bradley and Loftus 2000). This is supported by the genetic evidence provided by Hanotte et al. (2002),which also pointed to an exogenous but minor genetic influence of non-African origin from Europe and/or the Near East in the breeds of North and North-East Africa as well as localized areas of southern Africa. These African taurine cattle were also influenced by a slow genetic introgression by the zebu cattle (*Bos indicus*) of Asian origin. More recent genomic studies (Decker et al. 2014) of 134 modern breeds support the idea of three domestication events but also point towards evidence for later migration waves of animals to and from the three main loci of domestication. A study by Stock and Gifford-Gonzalez (2011) reported that although genetic evidence for African domesticated cattle is not as comprehensive as that for other forms of cattle, the available evidence suggests that domestic cattle in Africa are the result of wild aurochs having been introduced into local domestic *Bos taurus* (or *Bos taurus africanus)* populations. Indeed, African cattle of 5000 BP are distinctly different morphologically from the European humpless *Bos taurus* as well as Asian-originating Zebu (Grigson et al. 2000) and are hence believed to have a separate origin.

While scholars are divided about the likelihood of a third domestication event having occurred in Africa, *Bos* remains have been found at African sites in what is now Egypt, such as Nabta Playa and Bir Kiseiba, as long ago as 9000 BP, implying that they may have been domesticated in Africa. The earliest domesticated cattle in Africa have been found at Bir Kiseiba and Nabta Playa in South Egypt (11,000 BP–6000

BP) and Capeletti in Algeria (about 6500 BP), although early cattle remains have also been found at Wadi el-Arab (8500–6000 BC) and El Barga (6000–5500 BC). According to Wendorf and Schild (1980), the domestication of cattle in Africa happened 9500 BP in the Eastern Sahara near the Jebel Marra massif in north-western Sudan. Marshall and Hildebrand (2002) suggest another location on the eastern part of Tibesti in northern Chad. Thus, there is increasingly convincing genetic and archaeological evidence for domestication within Africa, and it is now generally considered that there are at least three auroch domesticates and that all of them are represented in Africa today.

The first major description of African domestic cattle was prepared by Doutressoulle (1947), while Epstein (1971) did the most comprehensive review, also conjecturing on the chronology of their introduction to the continent. A recension of this was presented by Mason (1984). There are also descriptions of cattle types by Stewart (1937), Gates (1952), Payne (1970), and Fricke (1979). Archaeological material was reviewed by Smith (1980), Muzzolini (1983, 1993), Epstein and Mason (1984), and Clutton-Brock (1989). Blench (1993) presented additional ethnographic and linguistic evidence for the prehistory of African cattle. ILCA (1979a, b, 1992a) and Shaw and Hoste (1987) made an overview of the distribution of the trypanotolerant cattle of West and Central Africa.

Over the past 25–30 years, the global science community, with significant leadership provided by the International Livestock Research Institute (ILRI) scientists, working with local scientists and international partners in Africa and Asia, has undertaken in-depth studies to help establish the origins of and genetic relationships among African cattle.

Rege (1999) and Rege and Tawah (1999) made attempts to do a comprehensive classification of present-day African cattle breeds and strains of various groups, including recent derivatives. This classification formed an important basis for the sampling of biological materials that followed and underpinned the study by Hanotte et al. (2002), which was the first comprehensive continent-wide molecular genetic study of African cattle.

The work by Hanotte et al. (2002) led to the reconstruction of the first genetic history of cattle in Africa, linking livestock to human history and providing a glimpse into the distant past of the peoples and civilizations of Africa (and Asia), and the publication has remained a reference on the history and geography of African cattle to date. The study has inspired several follow-ups to deepen the understanding of the current distribution of cattle genetic diversity and how this relates to the centres of cattle domestication in the Near East and the Indus Valley.

Subsequent autosomal and Y-specific microsatellite analyses have revealed the genetic relationships among the present-day African breeds and have detected little-to-no Asian Zebu or Middle East or European taurine influences among the indigenous West African taurine living within the tsetse fly zone. A major Asian Zebu influence, which probably started around the seventh and eighth century AD, is clearly visible among the cattle populations of Eastern Africa and the Sahel. These populations are the result of interbreeding between the African indigenous taurine and the Zebu of Asian origin. The predominantly taurine genetic background of the southern African Sanga supports the archaeological view of an early arrival of cattle in the southern part of the continent before the major Zebu influence in the Horn of Africa. These studies of the origin and history of present-day African indigenous cattle demonstrate their unique genetic background—both the taurine and the indicine.

Some of the studies that have informed the present-day understanding of the history, geography, and unique genetic attributes of African cattle include Grigson (1991),who provided alternative views on the origins of present-day African Sanga cattle, Frisch et al. (1997),who presented new evidence of the origins of southern African Sanga, and Hanotte et al. (2002), who examined the genetic signatures of the origins of African cattle populations and revealed dispersal history and current geographical distribution of various genetic backgrounds. Kim et al. (2017)

analyzed patterns of African cattle genetic variation by sequencing 48 genomes from five indigenous populations and comparing them to the genomes of 53 commercial taurine breeds. The highest genetic diversity was found among African Zebu and Sanga cattle populations. Kim et al. (2020) undertook a whole-genome sequence analysis of 172 indigenous African cattle from 16 breeds representative of the main cattle groups. The study identified a major taurine × indicine cattle admixture event dated to circa 750–1050 years ago, which supposedly shaped the genome of today's cattle in the Horn of Africa.

It is now well-established that African cattle carry a taurine maternal ancestry originating from the Near East taurine domestication centre(s), while the possible genetic contribution of the now-extinct African auroch (*Bos primigenius opisthonomous*) remains unclear (Decker et al. 2014; Bonfiglio et al. 2012). The pattern of introgression of the Zebu genome across the southern, eastern, and north-western parts of Sub-Saharan Africa has been well-documented using autosomal and Y-chromosome-specific microsatellite loci (Bradley et al. 1994; Hanotte et al. 2000; Freeman et al. 2004).

Taken together, available results strongly suggest that the earliest cattle in Africa were of taurine *B. taurus* type. Subsequent waves of migrations of humped cattle (Zebu or *B. indicus*) then reshaped the genomic landscape of African cattle (Hanotte et al. 2002; Bradley et al. 1994; Freeman et al. 2004). The origins of African and European cattle seem to be more closely related and quite distinct from Indian cattle, the relatively large divergence providing evidence for at least two separate domestication events, and these were presumably of different subspecies of the aurochs, *Bos primigenius* (Loftus et al. 1994). Today, the African continent is uniquely rich in cattle diversity, with the number of unique breeds or strains estimated to be between 145 (Rege 1999) and 150 (Mwai et al. 2015). The genetic distinctiveness between these cattle breeds/strains remains largely unknown, and it may be more appropriate to talk about African cattle ecotypes. The various types are adapted to local environmental conditions (e.g. high temperatures, long periods of drought, and vector-borne diseases), which largely restrict the use of pure exotic breeds of European origin. The origin and migration pattern of cattle in Africa is depicted in Fig. 3.1.

3.2 Present-Day African Cattle Breeds and Strains

Present-day African cattle populations can be classified into four broad categories: the humpless *Bos taurus* (the indigenous African taurine cattle); the humped *Bos indicus* (the Zebu), distributed widely in Africa; *B. taurus* × *B. indicus* derivatives (the Sanga), found mainly in eastern and southern Africa; and Zebu × Sanga types (Zenga), such as the Fogera and Horro of Ethiopia and the Nganda of Uganda. The taurine (humpless) type has two subgroups—Longhorns (*Bos taurus longifrons*) and Shorthorns (*Bos taurus brachyceros*)—both of which are restricted to West and Central Africa. While the Longhorns are represented by two breeds only—the N'Dama and the Kuri—the Shorthorn subgroup has numerous representatives. In addition, Africa is home to a number of recently developed commercial composite breeds that are products of systematic cross-breeding between one or more of the four categories and exotic breeds, primarily of European origin. This forms the fifth breed category. A final category consists of recent and ongoing imports of exotic cattle breeds reputed for dairy, beef, or dual purpose. The classification can, thus, be summarized as follows:

1. The indigenous taurine cattle of Africa
2. The Zebu cattle of Africa
3. The Sanga cattle of Africa
4. The Zenga cattle of Africa
5. African commercial composite cattle breeds
6. Well-established exotic cattle breeds in Africa

These cattle populations (covered in this chapter and Chap. 4) inhabit more than five distinct major agro-ecological zones. Overall, the Zebu cattle (and their crossbred derivatives) are common in the arid and semi-arid northern Sahelo-Sudanian zone as well as in the eastern part of the continent, including the highlands, whereas tau-

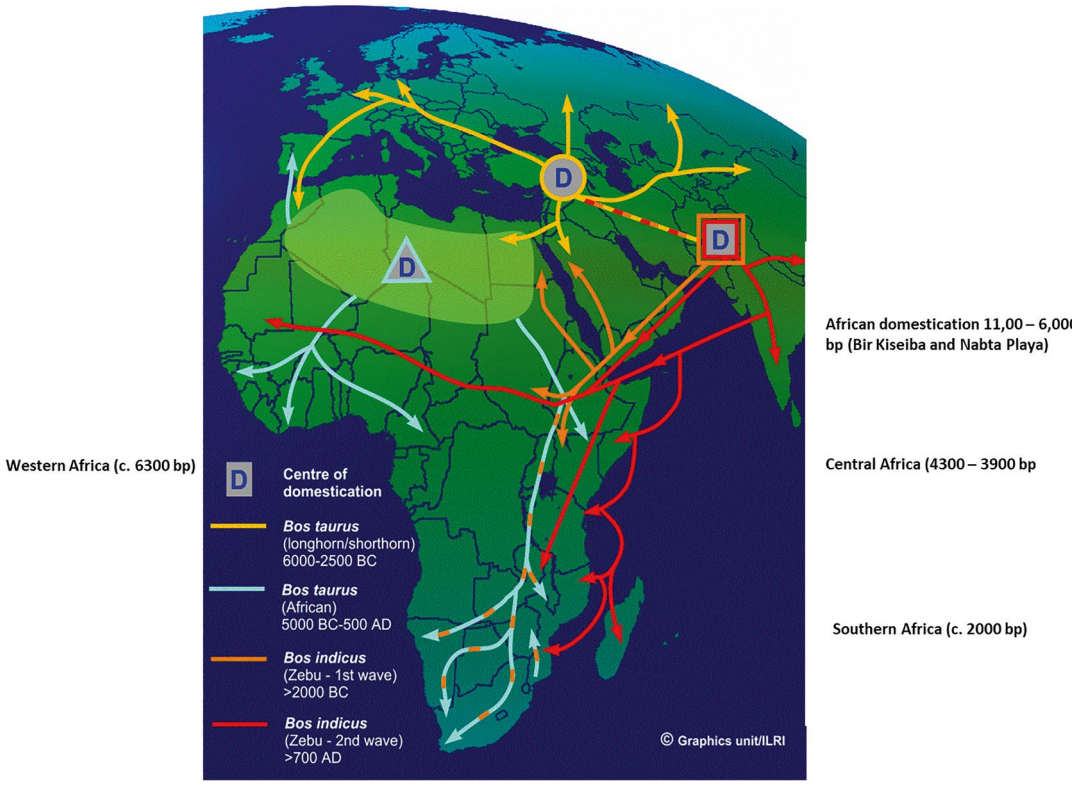

Fig. 3.1 Origin and migration patterns of domestic cattle in Africa. (Source: Modified from Mwai et al. (2015), licensed under CC-BY 4.0)

rine cattle today dominate the sub-humid and humid regions of West Africa, which are heavily infested with tsetse fly. The Sanga are predominant in the eastern African region, around the Great Lakes region, and in the southern part of the continent. The highest genetic diversity is among the African Zebu and Sanga cattle (Kim et al. 2017) (see Chap. 4).

The knowledge of the different categories of cattle on the continent and the uniqueness that they possess is crucial for developing strategies for detailed genetic characterization and have implications for the conservation and use of these genetic resources, as they point to population locations, phenotypes, and uniqueness. Africa is clearly a treasure trove of rich genetic diversity of cattle that are adapted to the diverse eco-zones and production systems covering a wide range of environments—from the harsh fringes of the Sahara Desert in North Africa, the drier areas of the Horn of Africa, through the wet tropical lowlands found along the Congo River, and on to the vast savannahs of Southern Africa. The spatial distribution of cattle breed types in Africa is depicted in Fig. 3.2.

The rest of this chapter presents a description of the indigenous taurine cattle of Africa, with a focus on habitat (ecological settings and production systems), their production and unique genetic characteristics, and their main uses. The next chapter (Chap. 4) undertakes a similar coverage of the remaining cattle groups—the Zebu and the Zebu–taurine derivatives, that is, the Sanga, the Zenga, and commercial composite breeds—and presents a summary of the major well-established exotic cattle breeds introduced into Africa over the past century.

3.3 The Indigenous Taurine Cattle of Africa

The taurine (humpless)-type cattle of Africa have two subgroups—the Longhorns (*B. taurus longifrons*) and the Shorthorns (*B. taurus brachyceros*). Both subgroups are restricted in their distribution to West and Central Africa. While the Longhorns are represented by two breeds only—the N'Dama and the Kuri—the Shorthorns are represented by a total of 15 breeds, strains, or ecotypes, all found in West and Central Africa, except one, the Sheko, which is found in southwest Ethiopia (Table 3.1).

Table 3.1 Humpless cattle breeds of Sub-Saharan Africa

Group and breed/strain	Synonyms	Location/country
Humpless Longhorns		
1. N'Dama	Boenca, Boyenca, Fouta Jallon, Fout, Malinke, Mandingo, N'Dama Petite, Fouta Malinke, Futa, N'Dama Peti, Gambian Longhorn	All coastal countries of West and Central Africa plus Mali, Burkina Faso, and Central African Republic
2. Kuri	Baharié, Bare, Borrie, Boundouma, Dongolé, Kouburi, Buduma, White Lake Chad, Boenca, Boyenca	Chad, Niger, Nigeria, Cameroon
Humpless Shorthorns (West and Central Africa)		
Savannah Shorthorns		
3. Ghana Shorthorn	Gold Coast Shorthorn	Ghana
4. Baoulé		Central African Republic, Côte d'Ivoire, Gabon, Burkina Faso
5. Savannah Muturu	Muturu	Nigeria
6. Somba	Atacora (Benin), Mango, Konkomba (Togo)	Benin, Togo
7. Doayo	Namchi, Namshi, Poli	Cameroon
8. Kapsiki	Kirdi	Cameroon
9. Bakosi	Bakuri, Kosi	Cameroon
Dwarf Shorthorns		
10. Ghana Dwarf Muturu	Muturu, Forest Shorthorn	Ghana
11. Lagune	Dahomey, Mayombe (Zaire)	Benin, Togo, Côte d'Ivoire, Congo, Gabon, Zaire
12. Logone	Toupouri	Chad
13. Bakweri	Muturu	Cameroon
14. Lobi	Lobo-Goui, Mere-Lobi	Burkina Faso
15. Liberia Dwarf Muturu	Muturu	Liberia
16. Nigeria Dwarf Muturu	Muturu, Forest Muturu	Nigeria
Humpless Shorthorns (Eastern Africa)		
	Shewa-Ghimira, Goda, Mitzan	Ethiopia

3.3.1 The Longhorn Taurine Cattle

As alluded to above, humpless (*Bos taurus*) Hamitic Longhorn cattle were believed to have descended from the first domesticated cattle populations of the humpless Hamitic Longhorn cattle in the 'Fertile Crescent', possibly in 9000 BC (Payne and Hodges 1997), and are considered to be the first cattle to be introduced into Africa by nomadic people via the land connection with Asia. From here, they spread westwards and southwards. More recently, combining genetic marker analyses with archaeological findings of indigenous cattle from the African continent indicates that the present-day indigenous African humpless cattle were the earliest, with a history dating as far back as 8000 BC (Gifford-Gonzalez and Hanotte 2011). The Longhorns are represented by only two breeds—the N'Dama and the Kuri. The two breeds are quite distinct in their morphology, adaptive and production attributes, and habitats (Rege 1999; Rege and Tawah 1999; Tawah et al. 1997) .

Out of a total of ten million trypanotolerant cattle in 1985 in West Africa, the N'Dama was the largest group, accounting for 49.5%, the Savannah Shorthorn was the next largest group with 20%, and this was followed by the Dwarf West African Shorthorn, which accounted for 1.0%. Zebu × N'Dama cross-breeds accounted for 12.6% and Zebu × West African Shorthorn for 16.9% of the trypanotolerant cattle population in the region (ILCA 1992a).

Except for the Kuri, which lives in a very special environment around Lake Chad where tsetse

flies have not been recorded, the taurine breeds (both the Longhorns and the Shorthorns) have developed in tsetse-infested areas and have developed varying degrees of trypanotolerance. The N'Dama is the best-known, the most numerous and the most widely spread of the trypanotolerant breeds. Although no recent comprehensive cattle census has been undertaken in West Africa, there is increasing cross-breeding of the N'Dama with Zebu breeds, and other than on-station herds, pure N'Dama population is decreasing at alarming rates on-farm across West Africa.

The N'Dama Cattle

***Other names*:** *Boenca* or *Boyenca* (Guinea-Bissau), *Fouta Jallon*, *Fouta Longhorn*, *Fouta, Malinke*, *Futa*, *Malinke*, Fouta Malinke, Madingo *or Mandingo* (Liberia), *N'Dama Petite* (Senegal), *Fout, N'Dama Peti, and Gambian Longhorn*

Incorrect names that are sometimes used: *Dama* and *Ndama*

Classification, Distribution, and Ecological Settings

The N'Dama is the most representative '*Bos taurus*' breed in West Africa and is believed to have originated from the Fouta Djallon plateau in Guinea (Conakry). From there, the N'Dama supposedly spread to the Sudanian and Guinean regions. Being trypanotolerant, the breed has been used for large-scale dissemination for grazing savannah across West and Central Africa, especially in the regions infested by the tsetse fly.

Today, the N'Dama is found in most West and Central African countries, namely, Guinea, Guinea-Bissau, The Gambia, Senegal, Sierra Leone, Côted'Ivoire, Mali, Burkina Faso, Togo, Ghana, Nigeria, Central African Republic, Gabon, Cameroon, Congo (Brazzaville), and the Democratic Republic of the Congo (DRC, former Zaire), particularly in the regions infested by tsetse flies (DAGRIS 2022). The estimated population size of the breed in West and Central Africa was about 4.9 million heads (Shaw and Hoste 1987), spread across the countries of West and Central Africa. An experimental population is also found in Kenya (owned by the International Livestock Research Institute).

Originally imported into the Democratic Republic of the Congo (former Zaire) from West Africa starting over seven decades ago, large-scale herds of this breed have been established and improved in Zaire by Compagne J. Van Lanckeic, a private company. The herd size is over 40,000 heads of pure N'Dama. Through a collaboration with ILRI, the ranch has been able to improve the mature weight of the breed by 30–50 kg without affecting inherent hardiness. In addition, large herds of N'Dama are kept exclusively for beef under ranching conditionsin Guinea. The breed has been selected and crossed with Jersey in Côte d'Ivoire since 1955 and has also been crossed with the Sokoto Gudali in Ghana following its original introduction in 1923. The N'Dama has also been crossed with the West African Shorthorn in Togo. Since 1986, the N'Dama has been exported from Senegal to the Virgin Islands, where they have been bred with Red Poll, and a new breed, the Senepol, has been created (Rege and Tawah 1999; Maule 1990) .

Physical, Adaptive, and Special Genetic Characteristics

The N'Dama has a compact body that is set on short legs of fine bone. It is of medium size, being 100 cm of height at the shoulder for cows and 120 cm for bulls, and with a short and broad head. The neck is thick and deep, the back is fairly broad, well-fleshed, and straight from withers to tail head, and it has a broad muzzle. The animals have no hump. The typical coat colour is fawn with darker extremities and lighter underside; common solid colour is light-to-dark fawn, grey, dun, light red, chestnut, or red with a black head. The belly and the lower part of the tail may be white. The average horn size is about 60 cm, and the horns are typically curved upwards and outwards or have a lyre shape, although there are different horn shapes and occasional polled individuals, especially in Sierra Leone and Guinea. The dewlap and umbilical folds are poorly developed. An N'Dama cow and herd are shown in Fig. 3.3.

In addition to its well-established tolerance to trypanosomiasis, the N'Dama is also considered

Fig. 3.3 A typical N'Dama bull and herd at Nsukka, Nigeria. (Photos by Dr E.M. Ibeagha-Awemu)

resistant to tick-borne diseases (Mattioli et al. 1993, 1998; Mattioli and Dempfle 1995). Specifically, tick resistance is mainly associated with Zebu breeds. Studies carried out in The Gambia show a higher resistance to ticks and tick-borne diseases in N'Dama than in Gobra (*Bos indicus*) cattle (Mattioli and Dempfle 1995). Tick resistance in N'Dama breed appears to be effective against those species with long hypostome, such as *Amblyomma variegatum* and

Hyalomma spp. In addition, the N'Dama is well-adapted to stressful humid and dry tropical climates. However, the breed is susceptible to rinderpest.

Production Characteristics and Production Systems

To date, the characterization of the N'Dama has predominantly emphasized the resistance to trypanosomiasis—which remains the trait of major interest in the production systems that dominate the habitat of the breed—and, to some extent, growth and milk production. More comprehensive characterization that includes objective measures of both inputs and outputs under local production environments is lacking.

The N'Dama is used in traditional production systems as a multipurpose breed providing milk, meat, manure, and traction. N'Dama oxen are considered good work animals, but cows are not considered very good milk producers. Much of the production data on N'Dama has been collected on government and university research stations and, hence, may not reflect the on-farm performance of the breed.

N'Dama cattle are known for their beef conformation. Average birthweight of 19 and 22 kg was reported in two high and zero trypanosomiasis risk areas, respectively (Feron et al. 1988), while respective bodyweights for mature cows in the two areas were 296 and 331 kg. The average adult weights range from 320 to 360 kg and from 250 to 270 kg for males and females, respectively (Payne 1970; Maule 1990; Starkey 1982, 1984; Portar 1991; Mason 1996). The dressing percentage is around 50%, and the meat has a very good flavour without much fat (Rege and Tawah 1999; Maule 1990).

Based on on-station data collected in a nucleus herd at Yamoussoukro station in Côte d'Ivoire, N'Goran et al. (2016) reported the age at first calving of N'Dama heifers between 20 and 65 months, with an average of 33.2 months. Calving intervals ranged from 300 to 822 days, and the average fertility rate in free mating was 86.8%. Mean birthweight was 17 kg for heifer calves and 19 kg for bull calves. Under ranching conditions involving grazing, salt licking, provision of minerals and dipping, the heifers have been reported to calve at 35–42 months (Maule 1990; Starkey 1984).

Least squares analyses of 668 lactations recorded over a 4-year period by Agyemang et al. (1991) in The Gambia showed a mean lactation length of 420 days, milk offtake of 404.3 kg, fat content of 5.1%, protein content of 3.2%, calf weaning weight of 88.1 kg, and calving interval of 641 days. A productivity index incorporating milk offtake, calf weaning weight, calving rate, and viability gave a mean annual of 140.6 kg of weaner calf plus the weight equivalent to milk offtake per 100 kg of cow metabolic weight. The index was higher than that which had been recorded for larger Zebu (*Bos indicus*) cattle managed under similar production systems elsewhere in Africa. The study concluded that the trypanotolerant N'Dama cattle appeared to be more productive than previously thought and suggested that the breed should be taken more seriously when promoting livestock development, especially in the tsetse-infested areas of Africa where other breeds cannot survive.

It must be noted that partial milking (in consideration of the needs of the calf) is the most frequent practice in the traditional herds of West Africa. In these circumstances, the milk yield (excluding consumption by the calf) is estimated at 70–100 kg per cow per year in most countries. The full lactation yield is about 500–600 kg (Mason 1984; Portar 1991). However, a dairy herd of N'Dama maintained in Sierra Leone from 1944 to 1952 reportedly averaged 540 kg over a lactation period of 283 days in one five-year period, with the highest yields recorded at 1150 kg per lactation (Touchberry 1967).

N'Dama cattle are remarkably productive under the moderate-to-high tsetse-fly-challenge areas (Fall et al. 2003), which characterize large areas of West and Central Africa, and they have been utilized in various production environments to meet the nutritional and livelihood needs of resource-poor farmers. The relatively high number of N'Dama cattle in countries like The Gambia, Guinea, southern Senegal, Guinea-Bissau, Mali, Liberia, Sierra Leone, Congo, and Gabon is directly related to its distinguishable

disease tolerance and relatively high adaptability to the local climatic conditions. Moreover, because of its unique characteristics, the breed has been crossed with the Jersey, Red Poll, Sahiwal, Fulani Zebu, Sokoto Gudali, and Simmental (Felius 1995).

An open nucleus breeding scheme (ONBS) for the N'Dama was established in The Gambia by the International Trypanotolerance Centre (ITC) in 1994 with the objectives of enhancing its genetic improvement and facilitating conservation through use (Dempfle and Jaitner 2000). The scheme focused on improving milk and meat production while maintaining trypanotolerance and other adaptive attributes. The involvement in the ONBS of multipliers and their association (Gambian Indigenous Livestock Multipliers' Association (GILMA)) in the dissemination of improved N'Dama bulls as well as the training of livestock assistants, farmers and multipliers, was an important component. Unfortunately, despite the promise demonstrated by this scheme, from 2006, GILMA collapsed as the programme suffered significant funding challenges, including a declining trend in human capacities and extension services. The injection of animals into the nucleus herd declined, and the release of new bulls into farmers' herds essentially stopped.

The Kuri Cattle

Other names: Lake Chad cattle, White Lake Chad, Buduma, Kuburi, Koubouri, Dongolé, Boudouma, Boundouma, Budumu, Budduma, Bare, Baharié, Borrie, and Kouri

While the origin of the Kuri is not certain, there are two theories. One theory considers that it is a pure Hamitic Longhorn, which descended from the ancient Egyptian or Hamitic Longhorn (Sect. 3.1), as depicted in the Egyptian drawings. According to this theory, the Kuri subsequently branched off the stream of the Hamitic Longhorn on its north-westerly passage from Egypt and migrated south-westwards through the Sahara corridor to Lake Chad. The other theory considers the Kuri to be of the Sanga (*Bos indicus* × *Bos taurus)* type that originated from the intermixture of lateral-horned Zebu and the Hamitic Longhorn in upper Egypt and present-day Ethiopia (DAGRIS 2022). The large and unique bulbous horns have facilitated the identification of its presence in rock paintings, which are estimated to be 4000–5000 years old (Epstein and Mason 1984; Baker and Manwell 1980).

Classification, Distribution, and Ecological Settings

Today, Kuri cattle are kept by the Kuri and Buduma ethnic groups. These groups are thought to have descended from the Kanembou tribe, which migrated to the Kanem district from Libya and the French Sudan in historical times.

The Kuri habitat is around the shores and islands of Lake Chad, bordering Chad, northern Cameroon, Nigeria, and Niger (in N'Guigmi Province). Its main habitat is southern Chad and north-eastern Nigeria. Most of the pure Kuri in the lake region are found on the islands of Djibadala, Koremeron, Debala, and Bagabol. Data on population estimates of Kuri cattle are quite outdated. ILCA (1992a) indicated populations of 39,560 heads in Niger and 13,947 in Nigeria. A total of 200,000 heads had been reported earlier by Renard (1972) for the entire Lake Chad Area. However, the restricted and rapidly shrinking habitat of the breed and the ongoing extensive cross-breeding with Zebu breeds in adjoining areas indicate that the breed is under immense pressure and is vulnerable.

The area in which the Kuri cattle are found is between approximately 130 and 160 North latitude and 130 and 170 East longitude and embraces the islands and shores of Lake Chad, both in Bornu Province, Nigeria, and in the Chad territory and N'Guigmi Province of Niger. The Kuri also extends into the Sudan Savannah zone to the west and south of Lake Chad and to the borders of the Sahelian zone in the north-west. The area is flat, with extensive marshes near the shores of Lake Chad, except the area that extends into the Sudan Savannah zone, which is undulating with sand dunes. The average elevation of the area above sea level is approximately 305 metres. The area has the Sudan zone climate with typically a clearly defined wet season extending over 5 months from May to September, while the remainder of the year is dry. During the period

from October to February, the days are hot and dry, with temperatures of over 43 °C. While the climate of the waterside areas of the lake is Sahelian, borders to the north have a sub-desert climate.

The diurnal range in both temperature and humidity is, however, considerable, and the nights can be cold and sometimes foggy. During the dry season, dry harmattan winds, carrying fine particles of dust from the desert, blow from the north and north-east and from the east to produce dry fog; during the wet season, monsoon winds blow from the south-west and west. Local secondary winds include daytime breeze from the lake when waterside temperatures are higher than those of the lake and night-time breeze from the land when a reversal in temperatures occurs. Winds are generally stronger in the day than at night. During the rainy months, storms move over the area from the south-west. At this time of the year, although temperatures are lower than in the dry season, the air gets humid, and the sky is frequently overcast.

The vegetation of Lake Chad is typically aquatic or semi-aquatic—a mixture of Sudan and Sahel zone vegetation. The best pastures are on the lowest highlands, which have been levelled by erosion. There are three types of vegetation on these lowlands: Temporarily flooded areas are dominated by *Sporobolus helvolus* and *Sporobolus spicatus*; the sandy bank vegetation is predominantly *Imperata cylindrica, Cynodon dactylon, Paspalindum geminatum*, and *Panicum subalbidum*; and the floating edge vegetation consists of *Phragmites mauritianus, Typha angustifolia, Cyperus papyrus*, and *Pennisetum* spp. Around the shores of the lake, in the marshy area, tall reed grasses of the papyrus type grow profusely, and grass species include *Andropogon* spp. and annual grasses such as *Aristidia mutabilis, Cenchrus biflorus*, and *Eragrostis tremula*. Along the banks of rivers and rivulets that drain into Lake Chad, there is a dense growth of *Commiphora africana, Acacia raddiana, Balanites aegyptiaca, Acacia senegal, Cadaba farinosa,* and *Calotropis procera*. *Cenchrus echinatus* and *Andropogon* spp. are the most common among the grass types.

Physical, Adaptive, and Special Genetic Characteristics

The Kuri (Fig. 3.4) is a tall animal, distinguished by its enormous horns and the absence of hump. Indeed, standing 15.2 cm taller than the average Zebu cattle in Nigeria, the Kuri is taller than most indigenous cattle of Africa. The height at withers can reach 180 cm in Kuri bulls. Cannon bone length averages 24.8 cm in bulls and 24.5 cm in cows. The head is long, with a straight profile and a wide forehead, to which the prominence of the orbital arches lends a 'degree of concavity'. The horns of the Kuri are its most remarkable feature, and both bulls and cows have horns. They are typically long (70–150 cm), with 'normal' horns being 60–90 cm long. The horns are circular in cross section, are about 20–100 cm in circumference at the base, and are lyre-shaped or crescent-shaped. Sometimes, however, the horns may be short, about 20–30 cm long. These horns may have a surface, which is roughened and ridged, and a cross section, which is flattened, so that their appearance is that of 'enormous ears'. The colouration of the horns is generally light except for the tips, which are black. The horns, although their appearance is massive and lend an aspect of great weight to the head, are not heavy as their structure is fibrous material that is light weight—being made of spongy material with a thin shell. Prunier (1946) had suggested that the bulbous base and spongy interior of Kuri horns was an adaptation for buoyancy. Loose horns can be seen in Kuri herds, and polled animals are not uncommon.

Reported linear body measurements of mature animals are highly variable, perhaps more a reflection of the variability in the definition of 'maturity' in the different studies than the actual variation among Kuri animals. The neck is short and flat. The ears are of medium size and are carried horizontally. The body is long and the top line straight, rising slightly from the withers, which, although thick, does not carry a hump. The hindquarters are of moderate slope. The tips of the dorsal vertebrae show a fused bifid structure. The limbs are long, and the hoofs are large and open. Overall, the body profile of a Kuri animal is straight, long, and disproportionate with

Fig. 3.4 A Kuri cattle herd in its Lake Chad environment and typical Kuri animals. (Courtesy: ILRI)

its cephalic mass. The most common coat colouration is white, but grey shading over the shoulders and the extremities, red, and red and white are sometimes seen. In areas further from Lake Chad, Kuri herds show evidence of a degree of Zebu interbreeding, and small cervico-thoracic humps may be seen as well as an increased proportion of broken and pied coat colours.

There is clear sexual dimorphism in the Kuri, with females having much smaller bodies than males. In addition, the head, tail, ear, and horn measurements of the cows are much smaller than those of the bulls, and both bulls and oxen are taller and broader at the chest than cows. Mature bulls weigh 500–650 kg, oxen weigh 500–750 kg, and cows weigh 360–450 kg.

The Kuri has been living in the hot aquatic milieu of Lake Chad for thousands of years and is well-adapted to this environment. They are excellent swimmers and are able to move around the aquatic habitat and thrive on the natural rangelands on the islands and the shores of the lake. They have a strong preference for fresh pastures. They are reputed for tolerance to insect bites and tend to 'ignore' the swarms of biting insects, which are found in their habitat during the greater part of the year. Their Zebu counterparts in this habitat are sensitive to these insects and have to be moved out of the lake basin before the peak of the biting insects. Kuri animals are, however, intolerant to heat and sunlight and are not able to withstand extended periods of drought. They,thus, tend to spend a significant part of the day immersed in water, with only their nostrils above water. They can graze in water that is as high as their bellies.

Kuri cattle are unable to survive outside the Lake Chad environment, and attempts to introduce them elsewhere have not succeeded, except around the Yobe River, where the environment is similar to that of Lake Chad. This has direct implications for the future survival of the breed since the water levels of Lake Chad are falling and the habitat is changing rapidly and could disappear over time. In addition, while the Kuri seems to be relatively immune to a range of indigenous parasitic diseases, the breed is susceptible to trypanosomiasis and piroplasmosis

(Queval et al. 1971). The Kuri is also reported to be susceptible to rinderpest and contagious bovine pleuropneumonia (CBPP) (Adeniji 1985; RIM 1992). Mortality rates of 27% have been reported in Kuri herds in Nigeria (RIM 1992), and this has been attributed to the CBPP epidemic.

Characterization of the Kuri serum has shown that total globulins are in greater proportion than albumins, which is a possible adaptation of the breed to its aquatic environment and may have implications for its immune responses. However, the relationship with the latter is not clear and requires further investigation.

Haemoglobin (Hb) gene frequency in the Kuri seems to suggest that the breed received its Hb^B through Zebu introgression. On the other hand, the complete absence of Hb^C in Kuri populations may be an indicator of its purity. Like *Bos taurus* breeds, the Kuri differs from the Zebu in their Y-chromosome—which is submetacentric in *Bos taurus* and acrocentric in the Zebu.

Production Characteristics and Production Systems

The Kuri cattle are raised in an unusual production system that integrates livestock production with flood-retreat farming and fishing. There is an abundance of pasture, and crop residues are not major feed sources in the system. The management system is traditional and extensive, with dependence on grazing. Flooding in the low-lying islands during the rainy season forces herds to be moved to the highlands and return to the islands during the dry season, a kind of transhumance. In the dry season, animals in herds of 30–35 heads follow their herdsmen in swimming from island to island in search of water-weeds as feed, a system that has been described as 'aqueous transhumance'. On the other hand, 'upland transhumance' is used to refer to the movement of cattle to the highlands during the wet season (June to September), as practised by the Yedina tribesmen. For both transhumance types, animals are split into transhumant and non-transhumant herds, with the latter comprising mainly lactating cows and calves.

The Kuri is reputed to be a good milk animal, and cows have traditionally been milked by their tribal owners. It is also considered to have great potential as a meat animal, with great fattening ability, but its owners do not use it as such. They are also used as pack animals but only sparingly, and they are not generally considered to be suitable for draft purposes. As a draft animal, the Kuri, on account of its heaviness, lethargic temperament, and slow movement, has poor performance. Even as pack animals, they suffer from the sun and get tired quickly.

Reliable information on Kuri lactation performance as well as milk composition is limited. The daily milk yield of the Kuri is reported to range from 3 to 6 kg over a 6–10-month lactation period. Tawah et al. (1997) summarized some historical lactation performances of the breed, including a record 2400 kg of milk reported in Nigeria over a 314-day lactation period and a 1259 kg lactation yield recorded over a lactation period ranging from 210 to 214 days in Chad. The lactation milk yield of the Kuri increases progressively from the first lactation to the fourth, at which point it plateaus and then declines over subsequent lactations. Tawah et al. (1997) referred to the results of a single study (based on an anonymous source) that estimated the butterfat, solids-not-fat, and lactose contents of Kuri milk at 4.2%, 8.3%, and 48.3%, respectively.

Queval et al. (1971) reported the average birthweight of Kuri at 25.0 and 22.5 kg for male and female calves, respectively. Tawah et al. (1997) have summarized some growth performance data: Yearling weights have been reported at 130 and 125 kg, respectively, for males and females, while corresponding weights at 2 years have been reported at 225 and 200 kg; animals on a 117-day experimental feeding on a diet consisting of fresh Napier (*Pennisetum* spp.) grass, cotton seed, and sodium bicarbonate supplement achieved an average daily weight gain of 0.62–0.65 kg (and consumed 6.9–7.4 kg per kg of weight gain) compared to extensively grazed controls on natural pastures, which gained 0.17 kg/day.

Kuri steers readily achieve 200–250 kg of carcass at 5 or 6 years of age on natural pasture with-

out supplementary feeding and up to 700 kg at slaughter when stall-fed (Renard 1972). A slaughter weight of 500–600 kg at the age of 5 years has also been reported (Tawah et al. 1997). The animals have good beef conformation (Renard 1972), and the meat is tender, juicy, and well-marbled (Renard 1972; Queval et al. 1971). Prime meat has been obtained from animals 4–6 years old in excellent fattening conditions. The most comprehensive slaughter information on the Kuri has been reported by Queval et al. (1971) and Renard (1972) based on the data collected from Fort-Lamy abattoirs in Chad. About 40% of Kuri carcasses weighed over 200 kg. These results have been summarized by Tawah et al. (1997). Kuri hides are reported to be of good quality.

Reproductive traits are the least documented of the Kuri performance traits. Age at first calving has been reported to range from 36 to 48 months (Adeniji 1985), and females have an active productive life of up to 12 years, during which they are able to produce an average of six to eight calves, with 12 calvings not being uncommon. Queval et al. (1971) reported 80% of cows in a Kuri herd producing four to nine or more calves in a lifetime. They breed throughout the year, although the usual breeding season is from July to October. Calving intervals have ranged from 15 to 18 months, and bulls are sexually mature at 3 years of age.

3.3.2 Shorthorn Taurine Cattle

Only limited publications exist on the Shorthorns of West and Central Africa, the earliest available ones being Jeffreys (1953) and Ferguson (1967). Although they are currently termed trypanotolerant, humpless Shorthorn cattle were historically distributed in almost all ecological zones. However, not much is known about the actual movements of Shorthorn-type cattle. Moreover, despite their wide distribution, humpless Shorthorns are not represented in rock paintings to the same degree as Longhorns.

It is speculated that the increasing aridity at the time of their introduction may have made it impossible for the Shorthorns to follow the southwestward migration route across the Sahara. This may explain the route taken westwards along the North African Mediterranean coast. Modern cattle in Egypt exhibit characteristics that resemble those of Shorthorn-type cattle, while existing breeds in the Libyan Arab Jamahiriya, Tunisia, Algeria, and Morocco are almost entirely of the Shorthorn type (Epstein 1971; Payne 1970; Rege et al. 1994a). It is highly likely that, like the Longhorns before them, the Shorthorns split into two routes around Morocco. One stream moved north into present-day France and the British Isles—the Jersey, Guernsey, and Kerry breeds are partly derived from this stock—and the other moved southwards and westwards, eventually coming into the rainforest zone of West Africa where, through exposure to trypanosomiasis, they became tolerant.

The movement of Shorthorn-type cattle southwards along the river Nile is much less documented. Stewart (1937) reasoned that, after entering Egypt from Asia, *B. taurus brachyceros* cattle spread southwards into western Sudan, as well as along the Mediterranean seaboard, as alluded to above. Hartmann (1864) and Keller (1896) recorded sporadic occurrence of humpless Shorthorns in the Sudan among cattle that were, by then, already generally humped. Faulkner and Epstein (1957) referred to a small number of cattle of this type in the Koalib Hills in the Nuba Mountains of the Sudan. This may be the same population that Mills (1953) reported to be tolerant to local forms of trypanosomiasis in a 'tsetse pocket' in the Nuba Mountains. It is possible that cross-breeding with the predominant Zebu-type populations in this area eventually occurred and, hence, Mason and Maule's (1960) conclusion that these cattle were of the Zebu type. Isolated populations of Shorthorns were also reported in East Africa (Stuhlmann et al. 1927). Similar cattle are reportedly found in the island of Socotra off the Horn of Africa and were also reported in the 1920s on the islands of Pemba and Mafia, off the coast of the present-day United Republic of Tanzania (Payne 1964), and also in Madagascar (Dechambre 1951). The Baria of Madagascar, for example, supposedly descended from the cross-

breeding between these cattle, Zebus, and a feral small-humped type. These Shorthorn populations may have resulted from movements further south of the introductions through Egypt and/or from a separate introduction through the Horn of Africa.

Doutressoulle (1947) reported that Shorthorns were brought to West Africa by the Berbers from southern Morocco. Domingo's (1976) suggestion that these cattle came through northern Nigeria from Egypt is not supported by Payne (1970) or Oliver (1983). From Morocco, the southern-bound Shorthorns supposedly spread between the Sahara and the Atlantic coast and the Guinea coast and the hinterland of Nigeria. Cameroon formed the extreme eastern and southern limits of their distribution in the region (Epstein 1971) .

Whatever the route might have been, short-horned humpless cattle are depicted among the prevailing Longhorns in rock paintings on the Bauchi plateau of Nigeria dating from the second half of the first millennium BC. Epstein (1971) states that the Shorthorns were the most common type of cattle in northern Nigeria before the Fulani invasions of about 1820. It is believed that they migrated from this area to the Atacora mountain regions in Benin, where they were later called Somba (Pagot 1974). Following the mountain chain along Benin, Togo, and Ghana, they supposedly populated the north of Togo and Ghana. Migrations of Akan people from Ghana to settle in Côte d'Ivoire (where they became known as the Baoulé tribe) brought the Shorthorns to the area. Through further migrations from Benin City in Nigeria, the Gulf coast was populated by the Shorthorns, eventually evolving to create the present-day local Shorthorn populations.

The elimination of Shorthorns from Chad, Sudan, and Ethiopia probably took place much earlier and was associated with the primary westward expansion of the Zebu. Traces of Shorthorns are still found in the east and south of Chad. It is believed that the population of Shorthorns in West and Central Africa owes its existence to its tolerance to trypanosomiasis, a competitive advantage over the Zebu. As has been alluded to, the Zebus were introduced much later and spread west and south, stopped only by the western rain-forest barrier. Cross-breeding between the Zebu and the taurine types is thought to have formed the Sanga type, which is the predominant type of cattle in the southern African region (Chap. 4). Present-day populations of Shorthorns in the Central African countries have resulted from imports in recent times, during and after the colonial era.

Modern-day populations or breeds of *B. taurus brachyceros* cattle in West and Central Africa include the Ghana Shorthorn, Baoulé, Savannah Muturu, Somba, Namchi (Doayo), Kapsiki, Bakosi, Lagune, Dwarf (Forest) Muturu, Bakweri, and Liberian Dwarf.

Broadly, Shorthorns can be divided into two subgroups according to size and conformation, namely, the larger Savannah type and the smaller Dwarf type. These, in turn, are associated with specific habitats. The larger Savannah type is predominantly found in the Guinean or Sudano-Guinean savannahs from Côte d'Ivoire to Cameroon (ILCA 1979a), while the smaller Dwarf (Forest) Shorthorns are found in lesser numbers in pockets of the coastal and forest regions. Whether the Dwarf Shorthorns are the descendants of a much larger progenitor type—dwarfing having resulted from generations of breeding—under the adverse effects of trypanosomiasis and mineral deficiency (Henderson 1929) or whether the larger Savannah type is a derivative of a Dwarf type—selection for larger size having occurred in the relatively tsetse-free savannahs—is still a matter of discussion.

3.3.2.1 Classification, Distribution, and Ecological Settings

(a) ***Muturu, Ghana Shorthorn, Baoulé, and Lagune***

The Muturu cattle are considered the only true native taurine cattle of Nigeria, the taurine Longhorn N'Dama having been imported to upgrade Nigerian Zebu for beef production and conferment of trypanotolerance on the trypanosusceptible (Zebu) breeds (Adebambo 2001). *Muturu* is a Hausa word meaning 'humpless', and in Nigeria and other English-speaking countries in West Africa (Ghana and Liberia), the name Muturu is used for Shorthorn cattle.

However, in Nigeria, no distinction is made between the Savannah and the Dwarf types (ILCA 1979b). The name Kirdi, a general term used by the Fulani for non-Muslim pagans (ILCA 1979b), is sometimes used for Muturu. These populations are found in south-west Nigeria and in the Middle Belt (Adeniji 1985). The past distribution of Muturu ranged across West and Central Africa, particularly in Cameroon, Liberia, Ghana, and Nigeria. Today, the Muturu is increasingly sparsely distributed in the humid forest zone and in a few savannah areas in Nigeria (Rege et al. 1994b). In French-speaking countries, the Savannah Shorthorns are called Baoulé and the Dwarf-type Lagune, although local names or synonyms are also used.

The Muturu breed is considered to have populated most of Nigeria before the arrival of Zebu (*B. indicus*) cattle in the seventeenth century (Felius 1995). Since then, the existence of Muturu has been consistently under threat due to farmer preference for the larger body size of the Zebu breeds. It is also considered that the rinderpest epidemics of the late nineteenth century exterminated many Muturu herds (Blench 1998). Today, the Muturu in Nigeria is mostly found in the forest zone and Guinea savannah of the Middle Belt. The *Dwarf (Forest) Muturu* is found in the rainforest just north of the coastal mangrove swamp, but a few hundred Muturu are reportedly found in the swamps of the states of Cross River, Edo, Delta, Ondo, Ogun, Lagos, and Rivers. The coastal forests, located south of the seventh parallel in the west and below the sixth parallel in the east, have constantly high temperatures (ranging from 26° to 28 °C) and high humidity, with an annual rainfall of between 1800 and 3000 mm. The rainy season lasts for 7–8 months between May and December, interrupted in August by a short dry season that becomes less distinct towards the south and disappears along the coast where there is virtually daily rainfall.

The habitat of the Nigerian *Savannah Muturu* is the 'derived' savannah and the Guinea savannah. The former, which covers a narrow belt between the Guinea savannah to the north and the rainforest to the south, is a climax vegetation created by the destruction of the original forest cover through constant shifting cultivation and population pressures (Olutogun 1976). Located in the higher rainfall belt of the country, the derived savannah represents a better natural grassland. Annual grasses such as *Brachiaria deflexa* and *Digitaria horizontalis* are among the first species to appear after the original forest is cleared. Perennials, including *Pennisetum purpureum*, *Panicum maximum*, *Ctenium newtonii*, *Andropogon tectorum,* and *Hyparrhenia rufa*, appear later. The Guinea savannah receives an average of 1500–2000 mm of rainfall, while the surrounding plateau and plains receive 1000–1500 mm, and the drier west receives 500–1000 mm. It is characterized by tall perennial grasses (1.5–3.0 m high) such as *Andropogon* and *Hyparrhenia* that grow in tussocks and provide wide ground coverage. *Pennisetum* and *Panicum*, among others, form the lower (1.0–1.5 m) layer (Fricke 1979). The type of grass is dictated by soil moisture. Dry soils are dominated by such plant associations as *Loudetia arundinacea*, *Ctenium newtonii,* and *Monocymbium ceresii*, while damp soils support grasses such as *Pennisetum purpureum*, *Chloris*, *Robusta,* and *Brachiaria* spp.

The habitats of both Muturu types (Forest and Savannah) fall within the tsetse belt. *Glossina fusca* is associated with the coastal forest, while the *morsitans* and *palpalis* groups are found in the savannah areas (ILCA 1979b).

In addition to the Muturu distributed in the south-eastern coastal area near Ada and Keta lagoons of Ghana, the country is also home to many Savannah Shorthorn types known locally as ***Ghana Shorthorn*** and, for which, the broader name West African Shorthorn is sometimes (ambiguously) used. The Ghana Shorthorn is distributed across the country from the Gold Coast to the north. They are particularly concentrated in the North, especially towards the north-western border around Bole, Wa, Lawra, and Tumu. They are also concentrated in the northern part of the Ashanti Region. A high concentration of relatively pure Ghana Shorthorns is also found around Bouna in neighbouring Côte d'Ivoire and near Gaoua in Burkina Faso (ILCA 1979b). In Liberia, typical Dwarf Shorthorns are found in

the eastern coastal areas of Maryland and Sinoe counties, while the less characteristic short-horned animals are found in Grand Bassa County and inland in the counties of Grand Gedeh, Bong, and Nimba.

The ***Ghana Shorthorn*** is found in all vegetation zones, including the humid forest zone. Its habitat is, thus, not limited to the savannah regions alone, despite its classification as a Savannah Shorthorn. The Guinean savannah woodland habitat of the Ghana Shorthorn is found north of the forest zone and stretches down to the south-eastern plains. It comprises a continuous cover of grass and low fire-resistant trees. Typical trees are *Parkia* spp., *Jacaranda* spp., and *Butyrospermum parkii*. There is a single rainy season from March to October in the northern half of the country, during which 1000–1200 mm of rain falls annually. Temperatures are very high, with a mean annual maximum of 34.5 °C in the extreme north. The humid rainforestin the south-west of Ghana receives an average rainfall of between 1210 and 3312 mm annually. The other forests are semi-deciduous, with a bimodal rainfall pattern and mean daily maximum and minimum temperatures of 30° and 21 °C, respectively.

The coastal savannah of Ghana receives an annual rainfall of 800–1000 mm between April and November. During the dry seasons (November and March), maximum daily temperatures can be as high as 32.2 °C. Mean monthly relative humidity is about 70 per cent at 15.00 h(GMT). *Andropogon*, *Brachiaria,* and *Hyparrhenia* spp. are the most common grasses of the coastal savannah. The south-eastern part of this area, near Ada and Keta lagoons, is the habitat of the few Dwarf (Forest) Muturu in Ghana. This is an unusual location for animals whose size is usually associated with a forest habitat. This area forms part of the Accra plains, a savannah region unusual for the coastal belt, which extends eastwards to the Togo border. Tsetse fly infestation in this area is reportedly low (ILCA 1979b).

The Baoulé are distributed in the north and central regions of Côte d'Ivoire (Pagot 1974) and are scattered throughout the forest zone (Shaw and Hoste, 1987). Some can also be found in the eastern parts of the country (Glattleider 1976). Baoulé cattle are grouped into several nucleus herds in the Korhogo (Sinematiali) Region, Bouna, Dabakala, and Central and High Nzi Valley, where they are herded by Peuhls (Fulanis). A study by ILCA (1979b) reported that the breed was still relatively pure towards Bouaké, Dabakala, and Bouna, but the situation is changing fast. In the Bouna Division in the north-east, they are called ***Lobi*** after a local tribe. Indeed, Baoulé in Burkina Faso are the same as the Lobi or ***Méré***, which are found in the southern part of the country. Rege et al. (1994a, b) proposed that the name Méré be restricted in the scientific literature to Zebu crosses with the Savannah Shorthorns in the area. The name is currently used to refer to both purebred Lobi and crosses of Zebu with Lobi (Burkina Faso), with Baoulé (Côte d'Ivoire and Burkina Faso), and with N'Dama (Côte d'Ivoire, Burkina Faso, and Guinea) and is, thus, rather confusing. In Mali, the term Méré (or ***Bambara***) is used for stabilized Zebu × N'Dama crosses. Although the name Lobi is widely used for the Savannah Shorthorn cattle in Burkina Faso, these cattle are quite like the Baoulé of Côte d'Ivoire (ILCA 1979b); the Lobi are somewhat smaller than the Baoulé in some areas. In addition, because of the proximity of the populations in the two countries and the cross-border movement of people and livestock, there is extensive interbreeding between Lobi and Baoulé.

Baoulé cattle were imported into the Central African Republic from Côte d'Ivoire and Burkina Faso between 1955 and 1969 and were subsequently distributed under the *métayage* system throughout the country (ILCA 1979b). Small numbers were also imported into Gabon for *métayage* operations in the 1940s (Shaw and Hoste 1987). In 1979, the Centre de recherche et d'élevage (CREAT) station at Avetonou in Togo purchased a herd of 120 Baoulé cattle from the Korhogo and Bouna regions of northern Côte d'Ivoire for trypanotolerance work (Morkramer and Dekpol 1984).

In both Côte d'Ivoire and Burkina Faso, the habitat of the Baoulé has a Sudano-Guinean cli-

mate. The climate is tropical and sub-humid with a dry season from November to April, during which the harmattan winds influence the area. The rainy season lasts from May to October, with a peak from July to September. The northern frontiers of Côte d'Ivoire have Sudanian vegetation with occasional islands of dense, dry forest over mostly savannah landscape. Farther south, the vegetation is sub-Sudanian, characterized by dry woodland and savannah. The Bagou River flows through the region from south to north, and its gallery forests form the major habitat of the tsetse fly of the *palpalis* group. In the dry season, *Glossina palpalis* and *G. tachinoides* are mainly confined to the riverine gallery forests. In the rainy season, however, *G. tachinoides* may be detected in forest islands at some distance from watercourses.

All the Baoulé (or *Lobi*) cattle in Burkina Faso are kept under village production systems (Shaw and Hoste 1987), while 99 per cent of Baoulé in the Central African Republic are kept under the *métayage* system (ILCA 1979a). This system is used to introduce cattle husbandry at the village level in regions where cattle rearing has not been a traditional activity. A basic breeding herd consisting of five to ten heifers and a bull is provided under contract to an individual or a small group of villagers by a commercial, governmental, or religious organization that maintains central breeding herds. The central organization undertakes the provision of technical assistance and veterinary inputs. In the event of loss resulting from natural causes, the animals are replaced without charge. The Baoulé cattle in Gabon are kept under the old *métayage* method or are generally left to wander freely with minimal supervision and no external inputs (Shaw and Hoste 1987).

The Lagune As alluded to above, Lagune is the name used for the Dwarf Shorthorn cattle in French-speaking West and Central Africa. These cattle are found mainly in Benin but also in Côte d'Ivoire and Togo, in a zone about 40 km off the coast (Epstein 1971). In Benin, Lagune are found mainly in the southern provinces of Atlantique, Mono, Ouemé, and Zou, an area stretching from the coast to the north of Abomey (Domingo 1976). In Côte d'Ivoire, they are located along the coastal region around Jacqueville, Abidjan, and Sassandra (ILCA 1979b). The population in Togo is mainly located in the maritime and plateau regions. *Logone* cattle (also known as *Toupouri*), found in southern Chad along the banks of the river Logone, are said to be similar to the Lagune (Anonymous 1950). Payne (1970) referred to *Lagone* rather than Logone, but this must be the same population. Whatever the origin of the Chadian population, it is quite likely that, given the habitat, it is genetically different from the coastal Dwarf Shorthorns. In particular, this population is unlikely to be trypanotolerant to the same extent as the Forest Shorthorns.

The introduction of Lagune cattle into the Democratic Republic of the Congo (former Zaire) began in 1904 when 50 heads of cattle were imported from Benin (Mortelmans and Kageruka 1976). Shortly afterwards, the breed was introduced at the Kangu Mission and at the Government Livestock Station at Zambi. Importation continued during the period prior to the First World War, and the animals multiplied and spread throughout Mayombe in Gas-Zaire, Kuilu in Bandundu, and Lisala and Bumba in the Equateur region of Zaire. These animals came to be known as Mayombe or Dahomey. Lagune cattle were later imported into Gabon from Zaire in 1945, 1948, and 1958 (ILCA 1979b). Some Lagune were also imported by Owendo Farms in Gabon from Benin in 1948 (Anonymous 1950). A few Baoulé cattle were imported into Gabon from Côte d'Ivoire around 1956 as well. These Lagune and Baoulé cattle in Gabon are now indistinguishable from each other and are commonly referred to as Baoulé (ILCA 1979b). They are found mainly in the north of Gabon as well as in the Ngounie and Nyanga regions.

In general, Dwarf (Forest) Shorthorns, including the Lagune, have a restricted ecological zone around the coastal forests of Côte d'Ivoire, Togo and Benin, the Atacora Mountains of Benin, and the riverine areas of Chad (for 'Logone'), as well as the tropical forests of Gabon, Zaire and the Congo, and the Guinea savannah of Zaire and the

Congo. The coastal forests are characterized by a Guinean or Sudano-Guinean climate with an annual rainfall ranging from 1200 mm in Benin to 2400 mm in Côte d'Ivoire. Two rainy seasons occur from March to July and from September to November. The most common tsetse fly species in these habitats are *G. palpalis*, *G. fusca*, *G. medicorum*, *G. pallicera pallicera,* and *G. longipalpis*. Trypanosomes commonly found are *T. vivax*, *T. brucei,* and *T. congolense*.

The humid tropical forests have an annual rainfall varying from 1600 mm to 3000 mm. In Gabon, this habitat is infested with *G. palpalis*, *G. tabaniforms,* and *G. haningtoni*. In the Guinea savannahs of the Congo and Zaire, rainfall varies from 1200 mm in the Congo to 2000 mm at the equator in Zaire. Gas-Zaire, Bandundu, and Equateur are the most heavily infested regions in Zaire. The main tsetse species here are *G. fuscipes* and *G. palpalis*. Common trypanosomes are *T. vivax* and *T. congolense*. Although the Logone breed is trypanotolerant, no tsetse flies are present in its habitat in the riverine areas of Chad (Landais 1980).

(b) ***Bakweri, Kapsiki, Doayo, Somba, and Bakosi***

A small population of the Dwarf Muturu is found in Cameroon at the foot of Mount Cameroon, between Buea and Victoria in the South-West Region, and is known locally as ***Bakweri***. Cameroon also has three localized subpopulations of the Savannah Shorthorn type, known as ***Kapsiki, Doayo,*** and ***Bakosi***.

Kapsiki cattle (also called ***Kirdi,*** as are the Nigerian Muturu) have historically been found around the Mandara Hills of Cameroon along the Nigerian border in the Margui-Wandala Division of the Far North Region between Mokolo and Bourrah, as well as around Mogode at the border with Nigeria. There are also a few Kapsiki herds on the Nigerian side of the border. The Doayo people keep a Savannah Shorthorn type of cattle in a small area in the north-western foothills of the Poli Mountains in the Bénoué Division of the North Region. These cattle are locally known as ***Doayo, Namchi*** (***Namshi***), or ***Poli***. Figure 3.5 shows a herd of Doayo (Namchi) cattle in Cameroon.

The ***Bakosi*** cattle are kept by a tribe of the same name located in south-western Cameroon, west of Nkongsamba on the border between the South-West and Littoral Regions. However, the cattle-rearing areas of the Bakosi people are limited to the north-eastern part of the boundary of the Bakosi tribe on the western slopes of Mount Manengouba in the Banghemu subdivision of the South-West Region. It has been reported (Epstein 1971) that the location of the Shorthorn cattle, otherwise mainly coastal, in the highlands of Cameroon, is as a result of the fact that their owners were forced to retreat from the fertile plains of the Diamaré and the Adamawa regions at the time of the Fula migration at the beginning of the twentieth century.

In Cameroon, the habitat of the Bakweri is around the foot of Mount Cameroon, between Buea and Victoria (present-day Limbe) in the South-West Region. This area has a humid forest climate with an annual rainfall between 1500 and 4000 mm. The habitat is similar to that of the Muturu in the forest areas of Nigeria and Liberia. The dominant tsetse species are *G. tabaniformis*, *G. nigrofusca*, *G. pallicera,* and *G. caligenia* (ILCA 1979b).

The name ***Somba*** is used for the Savannah Shorthorn populations in Benin (where the name ***Atacora*** is also used) and Togo (where they are also known as ***Mango***). The Somba tribe inhabits the area around the Atacora Mountains in Benin. This mountain range has enabled the Somba breed to be maintained pure in its original habitat. Somba cattle are particularly associated with the district of Boukombé, as well as with Natitingou and Tanguiete. The Somba are also found in Togo, where they represent over 50% of the national herd. They are raised by the Tamberma people, who are believed to have the same ethnic origin as the Somba of Benin (Avegan 1984). These cattle populations are concentrated in the north of Plateau Region; in Oti Division south of the Savannah Region, where they are known as Mango cattle; and in the Central and Kara regions, where they are called ***Konkomba***.

Somba cattle are principally found in the Sudano-Guinean savannahs, while the Kapsiki and Namchi inhabit the Sahelo-Sudanian zone,

Fig. 3.5 Doayo (Namchi) cattle at Wakwa, Cameroon. (Photos by Dr E.M. Ibeagha-Awemu)

with the Kapsiki being predominantly on the Sahelian side and the Doayo (Namchi) in the more Sudanian climate. The habitat of the Kapsiki cattle in the Mandara Mountains is at an altitude of 600–1000 m. The rainy season is traditionally between June and October, with the maximum rainfall occurring in August. Rainfall ranges between 500 and 850 mm, while minimum and maximum temperatures have historically averaged 8–10 °C and 32 °C, respectively. The dry season lasts for 7 months. It must be noted that these climatic conditions are significantly changing due to climatic variability.

The vegetation is savannah interspersed with such trees as *Isoberlina* spp., *Adansonia digitata*, *Boswellia dalzielii*, *Combretum* spp., *Daniellia oliveri,* and *Ficus populifolia*. The most common grasses are *Hyparrhenia hirta*, *Andropogon gayanus*, *Pennisetum pedicellatum*, *Cymbopogon giganteus*, *Rhynchelytrum repens*, *Thelepogon elegans,* and *Aristida* spp. The habitat of the Kapsiki breed is considered to be tsetse-free. The Bakosi area in Banghem is derived savannah merging into humid forest. Annual rainfall ranges from 2000 to 3000 mm. The level of tsetse fly infestation in the area is not fully known, but it is unlikely that there are any tsetse flies in the higher altitude areas, and varying degrees of infestation may possibly be found in the forests.

3.3.2.2 Physical, Adaptive, and Special Genetic Characteristics

(a) ***Muturu, Ghana Shorthorn, Baoulé, and Lagune***

The ***Muturu*** is a small and compact animal, very similar to the Lagune, but well-muscled and with a good beef conformation. Indeed, the Muturu are the smallest cattle breed of the Nigeria cattle and the smallest among the Shorthorns in West Africa, with a reported range in wither heights varying from 71 to 100 cm (Aboagye et al. 1994)—from extremely small Dwarf (Forest) Muturu (<89 cm tall at withers) to small Savannah Muturu (>89 cm tall at withers). The Nigerian Dwarf Muturu has been described as a smaller and purer *B. brachyceros* than the other Shorthorns in the region. Like the Lagune, the legs are thin and short, with the height to chest ranging from 37 to 49 cm. Sexual dimorphism is quite pronounced. Contrary to expectations, the males are generally smaller than the females, although they have well-developed and robust hind legs. The hump is absent and the dewlap is extremely small, typical of the Shorthorns. The Muturu head is long and relatively large compared to its body. The face is triangular in profile and slightly concave, with a flat and wide forehead. The nose is straight, and the muzzle is large and black. Typical Muturu animals are depicted in Fig. 3.6.

The horns of the Muturu are small and short, especially in the females, and thick at the base in the males. They can attain lengths of about 7.8 cm, with a basal girth of 16.6 cm and a basal core circumference of 13.2 cm. The horns are oriented outwards and forwards and laterally to the exterior, forming a 'C' in the females. Rudimentary horns also exist. Polled animals are also common. The ears are small and laterally attached below the horns. The neck is of average length and flabby and appears to be wider longitudinally. It is thin in the females and sturdy in

Fig. 3.6 A Muturu herd (**a**), bull (**b**), and cow with calf (**c**), showing typical black and white colour patterns. (Courtesy: Prof. O. A. Osinowo)

the males. The chest is wide and deep, and the back is well-muscled. The top line is inclined slightly forwards in the females and is horizontal in the males. The udders of the cows are poorly developed.

The Muturu has a multiplicity of coat colours, with plain black and black and white being the most common and typical of the Shorthorns (Maule 1990; Mason 1988). However, coats that are brownish black or dark brown with white markings have also been reported. Black or darker shade coats are common among the Forest type, while black and white or lighter shade coats are typical of the Savannah type.

Estimates of adult linear body measurements in Table 3.2 indicate a wide variation across breeds/strains and environments, especially in the females. It must be noted that substantial differences exist in body size measurements between the two ecotypes—Forest (Dwarf) and Savannah—in the region.

Muturu cattle have acquired hardiness and tolerance to tsetse flies, tick-borne diseases, and trypanosomiasis, as well as the ability to maintain an excellent body condition on grazing or browsing alone. Despite their reputed hardiness, Muturu cattle are extremely susceptible to rinderpest (Ferguson 1967). It is the well-recognized ability of the Muturu to thrive in the presence of the trypanosome challenge that has drawn much attention to the breed. Studies comparing the trypanotolerance of the Muturu, N'Dama, and Zebu under different combinations of trypanosome species have concluded that the Muturu was intermediate in its ability to withstand mixed infections. Results from a more recent study (Tijjani et al. 2019), which examined genomic regions in Muturu, which are under common signatures of selection with those in the more widely studied taurine Longhorn, the N'Dama cattle, including for adaptive immunity and heat tolerance, suggest shared mechanisms of adaptation

Table 3.2 Adult linear body measurements by sex and breed of Shorthorn cattle

Trait	Sex	Ghana Shorthorn	Baoulé	Kapsiki	Namchi	Lagune	Muturu
Body length *(cm)*	Male	143.0	120.0–121.2	114.0–142.0	125.0–145.0	121.4	86.5
	Female	111.4–122.7	108.6–112.3	115.0–132.0	110.0–130.0	108.6–119.7	93.5–107.0
Withers height *(cm)*	Male	115.5	100.1–105.7	105.0–116.2	100.0–110.0[a]	99.1	95.0
	Female	99.0–109.0	90.0–100.0	100.0–109.0	97.0–106.0	85.0–101.4	88.0–95.4
Heart girth *(cm)*	Male	169.0	140.5–140.7	135.0–148.0	140.0–159.0[a]	137.3	125.0
	Female	139.0–147.1	128.4–132.6	130.0–140.7	125.0–140.0	122.6–137.5	127.0–130.0

[a]Steers

to environmental challenges for these two taurine cattle. These results, while providing insights into the candidate genes under selection in Muturu, are forming a basis for the identification of genes and their polymorphisms linked to the unique tropical adaptive traits, including the trypanotolerance of the Muturu.

Muturu cattle have been reported to be sensitive to solar radiation and, therefore, are very shade-dependent. This behaviour is related to their low rate of cutaneous evaporation compared with that of the N'Dama and the Zebu (Amakiri and Mordi 1975). Therefore, an appropriate husbandry system for the Muturu should provide shade.

The hardiness of the Muturu is exemplified by its low mortality rates compared with those of other Shorthorns under similar management conditions (Aboagye et al. 1994). Its cumulative calf mortality rate at 1 year of age has been relatively low compared to those of other Shorthorns, both on-station and on-farm. Few studies have reported on the haemoglobin (Hb), albumin, vitamin D–binding protein, carbonic anhydrase, and transferrin (Tf) polymorphisms in the Muturu (Table 3.3). The Muturu has a different sequence of Hb than that of other Shorthorns and the N'Dama, an indication that they may be genetically different from the other breeds. However, Baoulé and Muturu cattle, with similar transferrin alleles, are different from the N'Dama, which also has the Tf^{s} allele (Braend and Khanna 1968). The presence of another blood factor—Z'—in the Zebu and not the taurine breeds (Muturu and N'Dama) is further evidence of different ancestries of these cattle types. These alleles differentiate the humpless Shorthorns and Longhorns from each other as well as from the humped Zebu.

The ***Ghana Shorthorn*** (Fig. 3.7) is a small-sized animal with good beef conformation. Its head and neck are both long, but the neck is thin and the forehead flat. It has short and thin horns, like those of the Lagune, averaging 20.3 cm in length. Unlike the Lagune and Muturu, however, polled Ghana Shorthorns are rare. The top line is concave, with a rising rump. The hump is absent, and the dewlap is poorly developed, typical of *Bos taurus* cattle. Ghana Shorthorns vary considerably in colour markings: black and white animals are common, in addition to other colour patterns such as solid black, white, and mottled black and white. The Ghana Shorthorn is considered to be tolerant to trypanosomiasis and tick-borne diseases and is adapted to the harsh hot, humid tropics. Ghana Shorthorns have also been shown to have good heat tolerance with substantial individual variation (Kahoun 1971).

The ***Lagune*** is the smallest of the West and Central African Shorthorns. Indeed, standing at 80–105 cm at the withers, it is thought to be one of the smallest cattle breeds in the world. Lagune cattle are compact, with a straight top line. The legs are fine and short, about 47 cm to the chest, with a cannon bone length of about 20 cm. Like the rest of the Shorthorns, it is humpless, with a poorly developed dewlap. The head is massive, with a rectilinear facial profile, and it has a conspicuous poll and protruding eyes. The head varies in length from 27 to 39 cm and appears longer than that of the other Shorthorns. However, the length of the body compares favourably with that of the other Shorthorns. The forehead is flat or slightly concave, with prominent orbits. The horns are imperfect, often thin, or flat and, sometimes, loose or absent. The horns are short, huge at the base, and round and pointed at the extremities. They measure between 14 and 24 cm in length. The surface of the horns is coarse, and they are lighter in colour at the base and darker at the extremities. They are cylindrical in the males and oval-shaped and obliquely forwards in the females. Drooping horns and polled animals are common. The neck is short, thick, and bulky in the bulls and thin in the cows. The rump is narrow in the cows and muscular in the bulls, with the tail ending in a 10-cm switch. The back line slopes down from the rump to the withers more steeply (about 3–5 cm) than in the typical Savannah Shorthorn. The udders of the cows are very poorly developed. The coat colour is usually plain black, black with white spots, or black and white. Even though coats tend to be pure black among the Dwarf Shorthorns, they are especially so among the Lagune. Red or red and white animals are rare, while fawn, dark grey, or spotted light grey individuals are frequently encountered.

Source: Aboagye et al. (1994), Ibeagha-Awemu et al. (2004)

The patchy red, brown, or red and white animals found in Côte d'Ivoire are believed to be an admixture with the N'Dama. The eyelids, the mucosae, and the hoofs are black, and the muzzle is black or brown and thick (ILCA 1979b; Maule 1990; Adeniji 1985; Mortelmans and Kageruka 1976; Agbemelo 1983). A typical Lagune bull is shown in Fig. 3.8, while Fig. 3.9 shows a Somba and a Lagune cow.

In Togo, Leclercq (1970) and Agbemelo (1983) reported that animals from the maritime region in the coastal savannah have significantly longer (116–121 vs 110 cm) and deeper (133–138 vs 129 cm) bodies and are taller (96–101 vs

Fig. 3.7 A herd of Ghana Shorthorn cattle. (Source: ILRI)

Fig. 3.8 A Lagune bull. (Source: Ahozonlin et al. (2022), licensed under CC-BY 4.0)

93 cm) than those from Assahoun in the humid forest zone. These trends may have resulted from differences in nutrition resources, the prevalence of parasitic diseases, climatic conditions, and other contextual differences. However, similar values have been reported for animals under coconut plantations and village conditions in the maritime region. Much lower measurements than these have been reported for herds in villages and palm plantations in Côte d'Ivoire (ILCA 1979b). The ratio of heart girth to height at withers of the Lagune (1.36–1.53) (Aboagye et al. 1994) is comparable to those of the European beef breeds, such as the Limousin and the Charolais, and indicates that the Lagune is more compact than the Savannah Shorthorns. Figures for young Lagune cattle show that at 3–4 years of age, they are similar in ratio of heart girth to height at withers with the mature Zebus—the Gudali and the Fulani—in the region (Aboagye et al. 1994). Domingo (1976) reported similar ratios for Lagune cattle from 1.3 to 1.5 and from 3.0 to 3.5 years of age. The Lagune and Somba are similar in morphology, particularly in terms of height at withers. A recent study has reported high morphological diversity in the Lagune cattle of South Benin

(**a**) (**b**)

Fig. 3.9 Typical Somba (**a**) and Lagune (**b**) cows. (Source: Vanvanhossou et al. (2021a), licensed under CC-BY 4.0)

based on body measurements (Ahozonlin et al. 2020).

Lagune cattle, like other Shorthorns, have been described as hardy, trypanotolerant, and adapted to the hot, humid tropical conditions typical of where they live (Maule 1990; Adeniji 1985). Their habitat is characterized by poor feed resources; a high prevalence of parasitic diseases, including trypanosomiasis; and very harsh climatic conditions. Even though these attributes have not been objectively quantified, the fact that these animals live and produce in the tsetse belt indicates that they have a certain degree of tolerance. Moreover, in a case study of Lagune and Borgou (a cross between the White Fulani and the Somba or the Lagune) herds located about 50 km apart but similarly managed, with the Borgou under light tsetse challenge at M'Betecoucou ranch and the Lagune under medium challenge at the Samiondji station, ILCA (1979a) reported that only 51% of positive cases of trypanosomiasis were diagnosed among the Lagune cows over a two-year period compared with 86% for the Borgou cows, with the former showing only 4.2% positively diagnosed animals per month compared with 11.5% for the Borgou.

The highest Lagune calf mortality rate (24%) was recorded on the Samiondji station, which was reportedly the result of a medium tsetse challenge (ILCA 1979a), followed by the *métayage* operations (15%) in Benin (Aboagye et al. 1994). The much higher abortion rate (8.6%) under Samiondji station conditions in Benin (ILCA 1979a) compared with that (4.0%) under conditions of the maritime region in Togo (Shaw and Hoste 1987) was considered an indication of the effect of trypanosomiasis. Mortality has ranged from 9.3 to 37.9% in the males and from 13.4 to 31.3% in the females (Agbemelo 1983).

Besides the morphological similarity alluded above, Lagune and Somba cattle have also been shown to have similar erythrocyte factors, except in the L and S systems (Table 3.3), further suggesting that these breeds are identical, separated only by a geographical barrier. Likewise, haemoglobin gene frequencies are similar in both breeds as well as in the Baoulé. The smaller size of the Lagune is obviously a consequence of natural selection in an environment characterized by poor nutrition, a high prevalence of parasitic diseases, and very harsh climatic conditions.

The ***Baoulé*** cattle vary in size from small to medium. They are straight and compactly built, with a good general profile. Baoulé cattle are short-legged, with a height at sternum of 46.8–48.5 cm. The Baoulé body conformation points to good beef animal qualities; however, they are not stocky. Udders and teats are retracted and degenerate. The Baoulé has a massive head with a straight profile. The forehead is large and flat in the males but slightly narrow between the horns and orbits in the females. The muzzle is large and black, and the ears are small, laterally located and upwardly oriented in some and

horizontally attached in others. The horns are short and sturdy, with a solid base, although they vary in form (crown, half-moon, or hook) in the bulls. In the females, the horns have a slightly different shape and are smaller and oriented obliquely forwards and upwards. The neck is thick and very strong in the males but short and thin in the females. Baoulé cattle, like all taurine cattle, are humpless, with a retracted and degenerate dewlap.

As in the Ghana Shorthorn, the Baoulé (see Fig. 3.10) has a multiplicity of coat colour patterns, although solid black or black and white flecking is typical. Fawn or pied-fawn animals are rare. Various shades of colours with irregular spots, such as small black mottles on a predominantly white coat, occur in some Baoulé populations. Cases of red-pied, grey and yellow, or yellow-pied Baoulés are not uncommon. In addition, Baoulé animals with red backs are common in some locations. Healthy Baoulé cattle have short, fine, and glossy hair (Maule 1990; Morkramer and Dekpol 1984).

The Baoulé is considered tolerant to trypanosomiasis, resistant to tick-borne diseases, and hardy to the hot, humid tropics. Trypanotolerance in the Baoulé (like the N'Dama) has been much more extensively studied (Akol et al. 1986; Maehl et al. 1987; Pinder et al. 1987, 1988; Duvallet et al. 1988) than that of the other Shorthorns. Results from studies have indicated individual variations in the natural resistance to trypanosomiasis.

Table 3.3 shows the allelic frequencies of the transferrin (Tf), haemoglobin (Hb), erythrocyte phosphoglucomutase (PGM), albumin (Alb), and carbonic anhydrase (CA) polymorphisms in Baoulé cattle. Transferrin polymorphisms are common in livestock. Except for alleles Tf^{B} and Tf^{f}, which are also found in the Zebu, only alleles Tf^{A}, Tf^{D}, and Tf^{E} are found in the Baoulé and N'Dama. The Baoulé, like the Somba and Lagune, has a different sequence of Hb alleles from the Muturu and the N'Dama. These humpless cattle generally lack Hb^{B} and Hb^{C}, which are present in the humped Zebu. Comparatively, the Baoulé and most other Shorthorns have predominantly Hb^{A} and traces of Hb^{B}, except the Muturu, which have predominantly Hb^{A} and traces of Hb^{D} (Bangham and Blumberg 1958; FAO 1976). Y chromosomes in the Baoulé and N'Dama are sub-metacentric as in the European breeds, while those of the Zebu and Zebu derivatives are acrocentric (Pagot 1985). The structure of this chromosome can, therefore, be useful in detecting the purity of these breeds and in tracing their evolutionary history.

(b) ***Somba, Kapsiki, Namchi, Bamenda, and Bakosi***

Fig. 3.10 A Baoulé cow. (Courtesy: Albert Soudre', Open Source: https://www.eurekalert.org/multimedia/722329)

The *Somba, Kapsiki, Namchi, Bamenda, and Bakosi* have generally been described as small Savannah Shorthorns, although variations exist within and among them. In general, these breeds have a much-reduced dewlap and umbilical folds, typical of *Bos taurus* cattle. Of these breeds, only the physical appearance of the Somba has been well-documented.

The ***Somba*** is not readily differentiable from the Lagune morphologically. It is a stocky animal with good beef conformation. It has a straight and compact body profile with a cylindrical trunk. The top line is straight but inclined forward in the females, although slightly convex in multiparous cows. It is horizontal but with a slight concavity near the back in the males. The Somba head is long and narrow, with prominent orbital arcades, presenting a concavity to its large forehead. The head droops on a short and thick neck in the males. In contrast, the neck is thin in the females. The horns are short and thin, arching above the head, and light at the base and darker towards the extremities. They are circular in cross section in the males and oval in the females and have an outward and forward orientation towards the extremities. Somba cattle with polled and drooping horns also exist. The ears are short and horizontally attached. The limbs are small and short, and the tail is long, extending from the pin bone to the hock. The muzzle and the area around the eyes of the Somba are dark, and its skin is darkly pigmented. Its coat is usually dark, either uniformly black, black and white, red and white, or pied, generally with dark extremities. Grey and brown coats are rare in the Somba.

The Somba has an average height at withers of 90–100 cm, heart girth of 130–137 cm, and body length from pin bone to shoulder of 105–120 cm at maturity (at least 5 years of age) (ILCA 1979b; Maule 1990; Domingo 1976).

The ***Kapsiki*** (Fig. 3.11) has horns of medium length, averaging 20–40 cm. It has short and glossy hair and supple skin. While there is a variety of colour markings in the Savannah Shorthorns, those of the Kapsiki are even more varied. Pied-black is the predominant coat colour in Kapsiki. Other colour markings include solid black, pied-red, solid white, fawn, pied-brown, red, dark brown, wheat grey, and mottled pied-black. The coat colour of the B**amenda** and ***Namchi,*** on the other hand, is uniformly black, black and white, or black with white spots, and in some cases, it may be brown or spotted brown (Fig. 3.10). The coat colour of the ***Bakosi*** varies from black to white, with more than half of the population either brown or black.

Adult linear body measurements of the Kapsiki have been elaborately studied under village conditions (Aboagye et al. 1994) and are considered useful in estimating body weights of young stock, especially under village conditions where weighing is often not done. Reported linear body measurements attest to the small size of these animals. In general, the males are taller and deeper-bodied than the females. Tawah and Mbah (1989) reported adult height at withers of 112–116 cm and 104–109 cm, respectively, for the male and female Kapsiki under station conditions in Cameroon. An estimate of 110 cm was reported by ILCA (1979b) for height at withers in mature ***Bakosi*** animals. Adult linear body measurements for the Kapsiki and Namchi cows are quite comparable. In general, the Baoulé, Somba, Kapsiki, Namchi, Bamenda, and Bakosi are very similar in size at maturity. However, they are shorter than the Ghana Shorthorn but taller than the Muturu.

Like the other Shorthorns in the region, Somba cattle are believed to have acquired natural tolerance to trypanosomiasis. Although somewhat tolerant to tick bites, they have been reported to be susceptible to infectious diseases such as rinderpest, foot-and-mouth disease, contagious bovine pleuropneumonia, and digestive tract infections of the young (Avegan 1984). The Kapsiki cattle are also believed to be adapted to the Sudano and Sudano-Guinean climate of their habitat. The trypanotolerance of Kapsiki cattle is doubtful as these animals have lived in an environment now believed to be free of tsetse flies. Indeed, Achukwi et al. (1997) demonstrated that the Kapsiki cattle have more Zebu introgression than the Namchi cattle, the latter being similar to the N'Dama cattle in trypanotolerance, while the Kapsiki are similar to the Gudali (Zebu) in trypanosusceptibility. Meanwhile, the Doayo (Namchi)

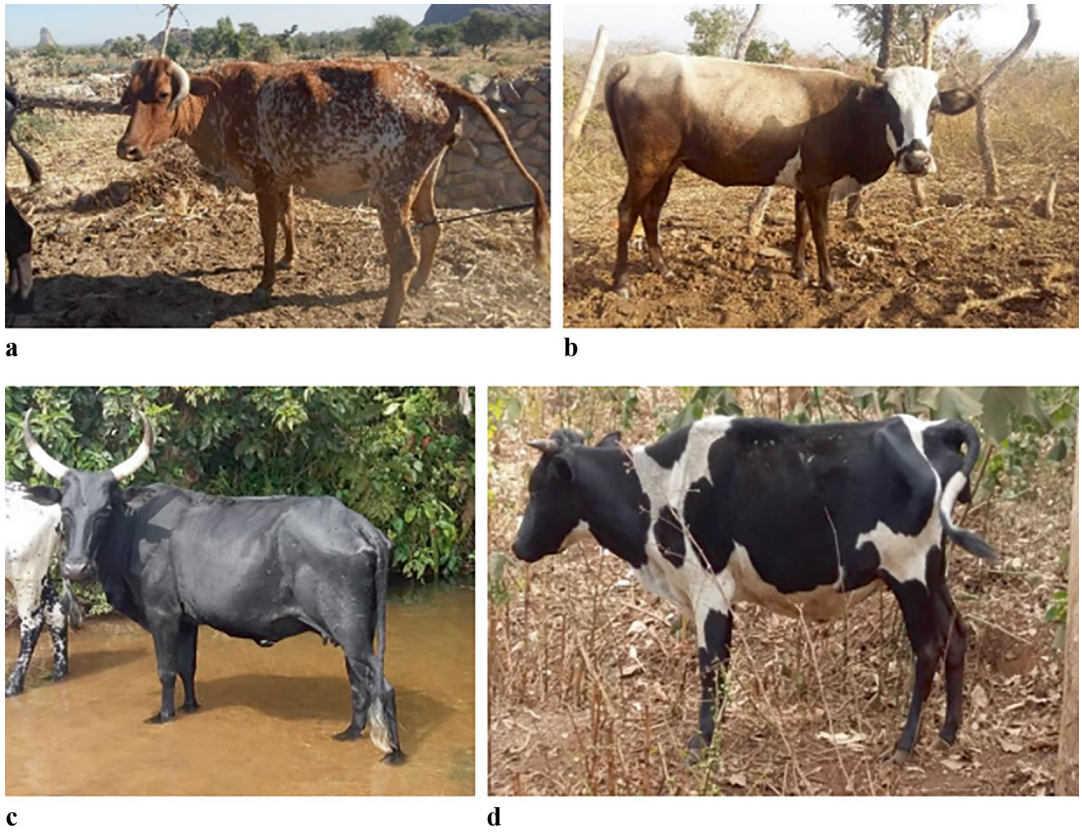

Fig. 3.11 Kapsiki (**a**), Namchi (**b**), Bamenda (**c**), and Bakosi (**d**) cows. (Source: Ojong et al. (2021), licensed under CC-BY 4.0)

is reported to be trypanotolerant, following challenges with T. congolense and Karankasso 83/CRTA/57 and under natural vector challenge (Achukwi et al. 1997, 2009).

The cumulative calf mortality rate to 1 year under improved conditions has been reported to average 12.9% for the Somba (ILCA 1979a) and 6.0 per cent for the Kapsiki (Tawah and Mbah 1989), which was much lower than the estimated 56.8% for the Kapsiki (Dineur et al. 1982) under village conditions. Moreover, the adult mortality rate has averaged as low as 1.9% for the Somba (ILCA 1979a) and as high as 5.9% for the Kapsiki (Tawah and Mbah 1989) under station conditions.

There is limited information on the genetic characteristics of these breeds in the literature. Phenotypic frequencies of the erythrocyte factors in Table 3.3 indicate that, except for the L and S systems, the Somba and the Lagune are genetically similar breeds. They also have similar haemoglobin gene frequencies. Vanvanhossou et al. (2021b) have identified the sub-region of bovine leukocyte antigen (BoLA) class IIb (including *DSB* and *BoLA-DYA*) in Somba cattle, which is uncommon in other African breeds. These results suggest the need for further investigations to understand its association with specific adaptation to endemic diseases.

3.3.2.3 Production Characteristics and Production Systems

The West and Central African humpless Shorthorns have reasonable levels of production, despite the hostile nature of their production environments. However, competition from the generally larger and supposedly more productive Zebu cattle restricts the ecological habitat of

trypanotolerant cattle to the tsetse-infested zones where the Zebu cannot survive. Indeed, the single most important factor determining the distribution of trypanotolerant cattle in the region and, to an extent, their production is the distribution of tsetse flies. This, in turn, is closely related to geographical relief, hydrography, climate, and vegetation. ILCA (1979a) presented a summary description of some of the features of the West and Central African regions where trypanotolerant livestock are found. The northern limit of the area is the 750-mm isohyet, above which is the dry, tsetse-free Sahelian zone. Between the 750-mm and 1500-mm isohyets is a transition climate that, in terms of rainfall and vegetation, can be divided into a Sahelo-Sudanian zone up to about 1250 mm and a Sudano-Guinean zone from 1250 to 1500 mm. Farther south, the humid tropical climate can be subdivided, mainly in terms of vegetation, into the Guinea savannah and forest zones. These zones differ in both amount and distribution of rainfall.

Superimposed on this broad zonal delineation are the effects of such local relief features as inland basins, river valleys, and mountains or highland areas. Between the coastal regions and the basins of the Niger River, Western Congo, and Lake Chad, prominent massifs are found. Local highland areas include the Fouta Djallon Ranges (1000–1500 m above sea level), the Guinea Dorsal (800–1752 m above mean sea level), the Togolese Mountains (600–920 m), the Jos Plateau in Nigeria (800–1690 m), the Adamawa Mountains in Cameroon (900–3008 m), and the Crystal Mountains in Gabon (600–1000 m). In addition to the coastal rainforest, the river basins, ramified by a network of rivers and streams, are also covered by dense rainforest.

The effects of these local relief features on local ecology and, hence, on livestock production can be considerable. For example, the Sudan savannah is characterized by high temperatures, low relative humidity of about 8 per cent in dry months, generally dry conditions with rainfall averaging 635 mm annually, an extended dry season of 5 or 6 months, and a single rainy season. The Atacora Mountains, however, have an annual rainfall of more than 1300 mm. In addition, the natural vegetation here is open woodland with grassland comprising *Andropogon*, *Hyparrhenia*, and *Imperata* spp. or woodland savannah with species such as *Isoberlina doka* and *Monotes kerstingii*. Similarly, the Namchi area, home of the Namchi, or Doayo, breed at the foothills of Poli Mountain in Cameroon, receives more than 1000 mm of rain over a period of only about 3 months. As has been stated, the distribution of trypanotolerant livestock is closely linked with that of the tsetse fly and is influenced by the degree of disease challenge presented by varying tsetse fly population densities and the ability of a species to transmit the disease. Tables 3.4, 3.5, 3.6, and 3.7 summarize some production characteristics of the Shorthorn cattle. These are then discussed in the sections that follow under each breed or group.

(a) ***Muturu, Ghana Shorthorn, Baoulé, and Lagune***

The Muturu are generally not milked (Fricke 1979; Ngere 1990) since their yield is just sufficient for their calves. Throughout most of southern Nigeria, however, milk is extracted from Muturu by native doctors for medicinal preparations. The animals and their hides are used mainly for ritual sacrifices and ceremonies (Fricke 1979), particularly funerals (ILCA 1979b). When a pagan dies, for example, one or more Muturu oxen are sacrificed, and the corpse is rolled up in the hides of the slaughtered animals, while the meat forms part of the ceremonial feast. Muturu are commonly kept for prestige or dowry purposes and are also used for draught in some areas (Adeniji 1985; Domingo 1976). They are, however, not widely used as work animals. Occasionally, Muturu cattle are slaughtered specifically to provide meat. Some villages own only a few heads, which scavenge around the homesteads.

Because of the wide distribution of the Muturu, it is difficult to make general statements about management practices, which range from permanent confinement with stall-feeding through to tethering and to year-round grazing. Grandin (1980) gave a detailed description of the Muturu-keeping systems found among the Egun in the 1970s, but significant changes have

occurred in these systems since then. Akinwumi and Ikpi (1985) also made a comprehensive presentation of the production systems of the Muturu in Nigeria. The Resource Inventory and Management Limited presented a detailed coverage of management systems of the Muturu in different regions of Nigeria (RIM 1992). These reports indicate a very wide variation in the systems of herding, feeding, and housing. Availability of labour and access to grazing land seem to be the overriding determinants of the type of husbandry system used. On the one hand, expanding cultivation in many areas, especially in Igboland, has either tended to discourage the keeping of Muturu or forced owners to turn to stall-feeding or tethering systems. On the other hand, some of the northern Muturu populations, such as those in the north-east and on the Dimmuk escarpment, have ready access to mountain pastures that are of no value as arable land and can, therefore, be grazed by cattle with little supervision without risk of damage to crops.

In Igboland, an estimated 45 per cent of the herds are taken out to graze, 45 per cent are tethered, and 10 per cent are permanently stall-fed. The animals are kept in enclosures surrounded by hedges (*oka-efi*) with built-in sheds for shelter during the night or in bad weather. Traditionally, these cattle were sacred (*juju* cattle) in this region and were considered the property of local deities or were dedicated to the shrine. With the decline in tradition and the destruction of shrines, however, many villages are without a bull, which is one of the threats to the survival of these cattle populations.

The Koma people of the Antlantika Mountains in Gongola State keep semi-feral Muturu, which are neither tended nor supplemented, on the slopes outside their villages. Individual animals required for sacrifice have to be hunted down, although by-laws were passed in the 1970s to restrict the hunting of Muturu to year-round cut-and-carry systems in Yorubaland. This has not worked very well, mainly because of the labour-intensiveness of stall-feeding. As a result, both free-range and stall-feeding are practised in Yorubaland.

Traditions and beliefs relating to the Muturu on the Jos Plateau appear to reflect the 'wild' nature of the animal (RIM 1992). Not only are

[b]Figures in brackets are ranges

the animals not milked, but it is also considered taboo to tie them up. In addition, ticks are not removed as they are considered to be harmless. In this area, cattle are confined during the night in pens set close to the compound. Manure from these pens is collected at the beginning of the rain to fertilize the fields.

Most Muturu in southern Nigeria are in the hands of private owners, whether individuals, the community, or traditional chiefs and royal families. The animals receive little care and largely survive by scavenging around the village. They are usually seen grazing and sleeping in the fields of community schools. In some areas, cattle ownership was historically limited to traditional rulers and highly placed chiefs from whom permission had to be sought before an animal was killed.

The Muturu village production systems can be classified into three broad groups: free-range, household (compound), and communal (cooperative). In addition to these, a few government stations such as Ado Ekiti, Imala, and Odeda keep Muturu (Akinwumi and Ikpi 1985). The free-range system has been associated with the 'wildness' of the Muturu (Fricke 1979; Akinwumi and Ikpi 1985). Household production systems are characterized by the provision of a shed and stall-feeding. Common feeds used in this system include cassava leaves, chopped tubers, yam peels, maize on the cob, fresh maize leaves, kola nut pods, and salt.

The communal production system is common in the states of Ondo and Rivers in Nigeria. In Rivers State, the usual system of management is to allow the cattle to range freely throughout the year. The semi-feral animals are not milked. They receive little veterinary care and are not given any supplementary feed. Little attention is paid to their breeding. These factors, plus the importation of Zebus from the north, make the disappearance of Muturu from Rivers State almost inevitable (RIM 1992). More organized communal systems also exist, however, where owners pool their animals, often uniquely tagged, and engage one or two Fulani herders. A tract of land is set aside within the village for housing. Local government authorities occasionally provide a kraal, within which improved pastures are developed and made available at a fee to the cat-

tle owners. This system was adopted decades ago in response to the persistent agitation of crop farmers over the destruction of their crops and has had differing results in different states. In Ondo State, the acceptance of this system has essentially ensured the survival of Muturu, while in the adjacent Bendel State, several communities were forced to slaughter their cattle because of constant pressure from crop farmers. This was considered a causal factor for the decline of Muturu populations in this state between 1977 and 1984.

The Muturu in Liberia are also kept under village conditions although commercial production was initiated on the rubber plantations of Liberian Agricultural Company and Firestone, as well as on private commercial farms. Under village conditions, these animals are rarely herded and receive very little care. In some cases, they are tethered to avoid crop damage (ILCA 1979b).

Growth and live weights Birthweights of the Muturu have ranged from 8.3 kg for calves born to heifers under 24 months of age to 12.1 kg for calves of heifers at least 24 months old under the environment of light tsetse challenge in the derived savannah. Heavier birthweights, averaging 16 kg, have been reported in high-altitude tsetse-free zones in the northern Guinea savannah. Weights at 6 and 12 months of age of 87 and 119 kg, respectively, have been reported at the Upper Ogun Ranch, while corresponding figures of 56–58 kg and 91–92 kg have been reported at Ado Ekiti and 37–39 kg and 61–71 kg at Vom in Nigeria. This trend is obviously the result of more intensive animal management, including routine prophylactic treatments and proper feeding, at the Upper Ogun Ranch than at the Vom Institute, given the pattern of tsetse challenge in these areas. This demonstrates that the effect of trypanosomiasis can be reduced through adequate feeding and regular prophylactic dosing.

Carcass characteristics Carcass weights have ranged from 90 to 100 kg, with dressing-out percentages of 46–53 per cent. Despite differences in live weight, dressing-out percentages of Muturu and Zebu cattle in the region are comparable, and the meat quality of the Muturu has been judged to be excellent (Ezekwe and Machebe 2005).

Reproductive characteristics Muturu cattle are considered to have good fertility, with the capacity to produce one viable calf annually. Furthermore, they mature earlier than the Zebu in the region. The Muturu compares favourably with the Baoulé and the Lagune and is better than the Ghana Shorthorn in age at sexual maturity under improved management. Also, the intervals between consecutive carvings were shorter under improved management (10–15 months) than under traditional village (18–24 months) systems. As with other Shorthorn and Zebu cattle in the region, heifers tend to have their first calves at an older age under village conditions than under improved conditions.

The age of Muturu bulls at first service under village conditions has been estimated at 4–5 years (ILCA 1979b). Even though these bulls are capable of year-round breeding, some studies have indicated seasonal changes in the characteristics of their ejaculates (Igboeli et al. 1987), including volume (1.8 and 2.3 ml in the dry and wet seasons, respectively), motility (36.2 and 37.7 per cent), and morphologically normal sperm (70.0 and 79.1 per cent). In general, semen characteristics of the Muturu are inferior to those of the Gudali and the White Fulani under similar conditions. In addition to producing low-quality semen, Muturu bulls have been reported to be generally shy and nervous (Nwakalor et al. 1979). Moreover, the low motility and sperm concentration, coupled with low amounts of fructose in the ejaculates (Igboeli et al. 1987), are major impediments to the processing of Muturu semen for artificial insemination purposes.

Milk production characteristics Since Muturu cows are normally not milked, data on their milk production are not well-documented. Nonetheless, lactation milk yields for lactation lengths of 120–216 days have been reported to

range from 127 to 421 kg (Fricke 1979; Olaloku 1976). Ezekwe and Machebe (2005) confirmed the low milk production of the Muturu and reported a butterfat content of 4.7 per cent and that the other milk constituents were within the values reported for tropical breeds.

Lagune cattle are mainly used for beef (Adeniji 1985; Domingo 1976; Mortelmans and Kageruka 1976), but, like the Muturu, they are poor milk producers. They are not used for traction. In Gabon, a multiplication herd of 53 heads of Lagune cattle was established at the Estuaire Region with the main objective of manure production (ILCA 1979b).

The management and production systems under which Lagune cattle are raised are mainly traditional, even though some animals are kept under improved conditions (Adeniji 1985). In Benin, Lagune animals graze freely on natural pastures, under palm trees and coconut trees, and on fallow land. There are no provisions for feed supplementation or for veterinary care. On the contrary, under improved conditions, such as at the Samiondji station, animals graze natural or sown pastures in fenced paddocks and receive veterinary attention.

Generally, Lagune cattle graze and roam freely around the villages (Agbemelo 1983). Under these conditions, the husbandry systems are no different from the free-range system under which most southern Nigerian Muturu populations are kept. Unlike free-range Muturu, however, Lagune cattle are reported to be docile. In Côte d'Ivoire, Lagune cattle are kept in areas where farmers do not traditionally keep cattle, and they are rarely herded. Lagune cattle in Zaire (the Democratic Republic of the Congo) also roam freely in small herds of three to six, living on forest undergrowth and fallow land. They seek grazing everywhere and sometimes traverse long distances. This is like the situation in the Congo (Congo-Brazaville), where the animals are kept exclusively in village herds. As alluded to above, Lagune cattle imported into Gabon from Zaire were introduced at the village level through *métayage* operations (ILCA 1979b). Here, they were kept in herds of seven to 12, roaming freely during the day and penned at night. They were seldom given mineral supplements and were not sprayed against ticks. These animals were originally intended for Gabonese farmers, but some were sold to immigrants from Cameroon, who kept them under the same conditions for commercial purposes.

Growth and live weights Birthweights of Lagune have averaged 10–12 kg under village conditions, while growth rates and yearling and mature weights varied substantially. Rege et al. (1994c) reported that the mature weight of Lagune range from 180 to 280 kg in males and from 165 to 262 kg in females.

Carcass characteristics Dressing-out percentages for the Lagune have ranged from 48 to 54 per cent. Despite differences in carcass weight between the Lagune and Somba cattle, their dressing-out percentages are quite similar under village conditions.

Reproductive characteristics Age at first calving of the Lagune has ranged from 24 months under improved village conditions to 60 months under traditional village conditions. Mean calving intervals have varied from as short as 12 months under station conditions to as long as 24 months under village conditions, while calving percentages have ranged from 34 per cent under traditional management to 70 per cent under improved management. Most of the Lagune cows (74 per cent) tend to calve at least every 2 years under village conditions in Togo, with as few as 13 per cent calving every 3 years and the rest calving annually (Agbemelo 1983). The calving rate is related to the tsetse challenge, although the Lagune performs better under a medium challenge than do the Borgou under a light tsetse challenge (ILCA 1979a). Lagune females are known to calve without difficulty (Agbemelo 1983).

Milk production characteristics The lactation yield reported for the Lagune breed by Agbemelo (1983) under village conditions was higher than the available estimates for the Baoulé and the Somba under similar conditions. Daily milk yields ranging from 1.5 to 2.0 kg over lactation lengths of 120–225 days have been reported under village conditions. Milk butterfat in these animals has been estimated at 6.2 per cent, which is like that of the Zebu, Baoulé, and Somba cattle but higher than that of the Ghana Shorthorn and Holstein Friesian cattle.

Ghana Shorthorns are poor milkers (Maule 1990) and so are generally not milked. Montsma (1960) concluded that the milk yield of Ghana Shorthorns was too low to warrant the sale of fresh milk without adverse effects on the growth and general well-being of their calves. Moreover, when milked in the absence of the calf, they go dry within a few weeks (Ngere et al. 1975). However, the breed has good conformation for meat production (Domingo 1976) and yields reasonable beef carcasses (Ngere et al. 1975). They are also used for draught.

Over 99 per cent of Ghana Shorthorns are kept in village herds (Shaw and Hoste 1987). Most cattle owners in Ghana are resident farmers, but town dwellers are increasingly becoming absentee cattle owners using hired herders, usually the Fulani. In such situations, the herders milk the animals, which forms a large part of their salary. Cattle are grazed on communally owned land. In many cases, especially in the main livestock region in the north, animals of several households are herded together and tended by village children, partly because the animals have good temperament (ILCA 1979b). Animals are penned at night. In the south-east, a herd may be allowed to graze on a farmer's land in exchange for the manure produced. In northern Ghana, herd sizes are usually small, with a typical family owning five to 20 heads of cattle. A high percentage of oxen, up to 10 per cent of a herd, are kept in areas where they are used for draught.

Growth and live weights Birthweights of the Ghana Shorthorns have ranged from 17 to 20 kg (see Table 3.4). Growth rates in the literature reviewed varied considerably, as did weaning and mature weights. In general, the performance of the Ghana Shorthorn (the Savannah type) has been better than that of the Dwarf (Forest) Shorthorn type. The wide range (64–154 kg) of weaning weights in Ghana Shorthorns may be the result of the variation (7–9 months) in weaning age, in addition to differences in management. Supplementation studies have shown that proper feeding can improve the growth performance of the animals. Mature weights on-station ranged from 163 to 380 kg and were, on average, higher than those on-farm, which varied from 170 to 200 kg. The variation in mature weights may also be associated with the lack of precise age at maturity in these studies.

Carcass characteristics Slaughter and carcass weights of the Ghana Shorthorn averaged 250 and 125 kg in the males and 192 and 102 kg in the females, respectively. Corresponding dressing-out percentages were 50 and 53 per cent. An on-station study of a sample of 32 Dwarf Shorthorns (Appiah 1988) in the humid forest zone produced slaughter and carcass weights of 142 and 67 kg, respectively, and yielded a dressing-out percentage of 47.3 per cent.

Reproductive characteristics The mean age at first calving of Ghana Shorthorn was better on-station than on-farm (Shaw and Hoste 1987; Cockcroft 1977). This is clearly the effect of poor nutrition in village herds. Likewise, the mean calving interval ranged from 15.4 to 18.6 months for the Dwarf (Forest) Shorthorn and from 9.3 to 30.8 months for the Savannah-type Shorthorn. Ngere and Cameron (1972) reported a much shorter calving interval of 13.8 months for Ghana Shorthorns under an improved production system. The annual calving rate, defined as a proportion of the number of calves dropped to the number of cows mated per year, has been estimated to be slightly higher for the Ghana (Savannah) Shorthorn than for the Forest type. This is obviously the result of the different tsetse

challenges in the two agro-ecological zones. Under improved conditions, the calving rate has ranged from 60 to 70 per cent for Ghana Shorthorn cows.

Milk production characteristics The total lactation milk yield of Ghana Shorthorn has been estimated using the weigh-suckle-weigh method, and results have shown that improving the level of concentrate feeding from late pregnancy through lactation increases the milk yield of the Ghana Shorthorns, up to as much as 1002 kg in 252 days. Rege et al. (1994c) reported a variation in lactation performance of cows from a milk yield of 5 kg produced over a period of 9 days to 3059 kg over 454 days. Normally, Ghana Shorthorn cows lactate for no more than 10 months, with a daily milk yield of at least 0.9 kg. However, this variation points to the potential for genetic improvement. In the absence of the calf, Ghana Shorthorn cows, like Zebu cows, tend to dry off within a few weeks of lactation. There is only limited data available on the milk composition of Ghana Shorthorns. Compared with the Holstein Friesian (4 per cent), Zebus (4–5 per cent), and some of the other Shorthorns (5–6 per cent), the Ghana Shorthorns' milk is low in butterfat (1.3 per cent) and proteins (3.2 per cent) (DAGRIS, https://dagris.info/ko/node/8359).

The Baoulé Unlike the Ghana Shorthorns, milking is practised in some Baoulé herds in northern Côte d'Ivoire (Godet et al. 1981). Here, herders usually receive a salary and all or part of the milk from the herds. Among the Lobi people of Bouna in the Northern Region of Côte d'Ivoire, milking is rarer than elsewhere—less than 50 per cent of the herds were reportedly milked, and only 25 per cent of these were milked regularly (Godet 1976). As has been noted, sales for cash represent an important cattle function in these production systems. In Baoulé herds, there appears to be a high offtake of young males between 2 and 4 years of age. Results from a survey carried out in Dabakala, Korhogo, and Bouna in Côte d'Ivoire (Poivey and Seitz 1977) revealed that herds consisted of 31 per cent males and 69 per cent females, with virtually no steers and an insignificant proportion of males over 2 years of age. Some herds had as many as six adult (mature) bulls. These obviously function as the breeding bulls at the village level in communal pastures. About 99 per cent of the cattle are kept under village conditions (Shaw and Hoste 1987), and the rest are kept in research stations and ranches, most of which are government-owned. In the north of Côte d'Ivoire, Baoulé cattle from one village are often herded together by hired Fulani herders who also milk the animals. Calves are separated from their dams in the evenings on return from grazing. In the mornings, they are allowed to suckle to stimulate milk let-down, facilitating milk offtake. Generally, a maximum of three teats of the udder are milked, after which calves are allowed to consume the remainder of the milk (Godet et al. 1981).

Growth and live weights Soro et al. (2015) undertook a comprehensive study of the morphometrics of Baoulé cattle in Côte d'Ivoire, including adult birthweights (Table 3.8). Birthweights of the Baoulé have ranged from 9 kg under village conditions to 16 kg under improved conditions, and growth rates and weaning and mature weights have varied substantially. Mature weights have ranged from 160 to 300 kg in males and from 150 to 240 kg in females (Rege et al. 1994c). Supplementary feeding yields substantial improvements in the growth performance of the Baoulé (Kouakou 1984; Tiemoko et al. 1990).

Carcass characteristics Only limited information is available on the carcass traits of the Baoulé. Carcass weights have ranged from 90 to 200 kg. Despite live weight differences, carcass weights of the Baoulé, the N'Dama, and the Sahelian Zebus are comparable. Dressing-out percentages are moderate (50 per cent), with percentages ranging from 53.2 to 54.8 for Baoulé cattle under station conditions in Côte d'Ivoire. A study by Tidori et al. (1975) reported that Baoulé

Table 3.8 Birthweight and linear body measurements of Baoulé cattle in Côte d'Ivoire

Parameters	Male (n = 44)	Female (n = 121)
Body weight (kg)	184 ± 39.9[a]	191 ± 36.5[a]
Heart girth (cm)	128 ± 10.3[a]	130 ± 9.65[a]
Height at withers (cm)	94.1 ± 5.25[a]	94.9 ± 5.48[a]
Horn length (cm)	14.8 ± 7.93[a]	15.6 ± 8.59[a]
Ear length (cm)	15.0 ± 1.37[a]	14.9 ± 1.51[a]
Body length (cm)	120 ± 7.43[a]	122 ± 10.1[a]

carcasses have a poor finish, with a 0.5-per cent fat index (defined as the weight of kidney fat as a percentage of hot carcass weight), against the recommended 2 per cent. Thus, Baoulé meat can be classified as poorly marbled.

Reproductive characteristics Age at first calving of the Baoulé has ranged from 24 months on-station to 56 months on-farm, while calving intervals have ranged from 11 to 37 months under station conditions. Chicoteau (1989) reported results from experiments carried out in Burkina Faso using both hormonal and behavioural criteria, which demonstrated that Baoulé females reach puberty at an average age and weight of 14 months and 125 kg, respectively. Despite differences in weight, Baoulé and European heifers are quite comparable in age at puberty. Moreover, Baoulé cattle reach puberty much earlier and are reportedly more fertile than Zebus and other Shorthorns in the region (Tidori et al. 1975). Calving rates have ranged from 32 to 85 per cent under station conditions, although a calving rate as high as 85 per cent was reported (Shaw and Hoste 1987) from a sample of 44 *métayage* herds in the Bossenbélé area of the Central African Republic. Given the difficulty of deriving a true calving rate in village herds, where immature heifers are usually grouped together with breeding females, some researchers have previously proposed that the term 'fecundity rate', defined as the number of calves dropped per 100 breeding-age females per year (Glattleider 1976), be used as a fertility measure in village herds. The fecundity rate of Baoulé has ranged from as low as 28 per cent in village herds in the Central African Republic to 85 per cent in some station herds in Côte d'Ivoire. Godet et al. (1981) pointed out that the extraction of milk for human consumption, in addition to affecting calf growth (Hoste et al. 1983), has a depressing effect on the fertility of the Baoulé.

Information on post-partum behaviour, sexual function, and cyclicity in cattle can be used to improve herd fertility. Although such studies are generally lacking for the West African Shorthorns reviewed here, a few have been made on the Baoulé (Chicoteau 1989; Djabakou and Grundler 1988). For example, it has been reported that the duration of uterine involution is between 30 and 34 days post-partum in lactating Baoulé cows (Chicoteau 1989; Hoste et al. 1983). This has a significant influence on the post-partum resumption of ovarian activity, the ability of the cow to breed again, the length of the calving interval, and the calving percentage. Moreover, post-partum resumption of cyclicity, an important determinant of the duration of the calving interval, takes about 57 days in lactating Baoulé cows (Chicoteau 1989), although it can be longer than 160 days (Meyer and Yesso 1988). Tidori et al. (1975) reported that sexual cyclicity in the Baoulé cow is significantly influenced by season, which is clearly a reflection of the effect of seasons on the nutritional status of animals in this pasture-dependent systems.

Male reproduction has been better documented for the Baoulé than for the other Shorthorn breeds in the region. Chicoteau (1989) reported the average age and weight at puberty as being 18 months and 155 kg, respectively, taken from a sample of 15 young Baoulé bulls in Burkina Faso. Despite the differences in their weights, Baoulé and White Fulani bulls reach puberty at comparable ages. Baoulé bulls were reported to have attained about 61 per cent of their mature

body weight at puberty. Chicoteau (Tiemoko et al. 1990) reported that, although young Baoulé bulls ejaculate first at 17 months of age, they produce first motile spermatozoa only after 30 months of age. The semen quality of Baoulé bulls is mediocre, which is indicated by their pubertal semen characteristics: 0.85 per cent motility, 0.8 ml sperm volume, 6.0 × 107/mm^3 sperm concentration, 40 per cent live sperm, and 85 per cent abnormal sperm. Chicoteau (1989) reported scrotal circumferences of 23 and 27 cm in pubertal and adult Baoulé bulls, respectively. This measure is used for the early evaluation of bull soundness and fertility.

Milk production characteristics Milk yield estimates under station conditions have been lower in the Baoulé than in the Ghana Shorthorn but generally higher than those of the Somba under village conditions. Milk yields have ranged from 118 to 387 kg over lactation periods of 279–341 days under village conditions. The month or season of calving seems to have a more significant effect on milk yields of the Baoulé than parity (Hoste et al. 1983), which is a further indication that nutrition is perhaps the most limiting factor. Information on the composition of Baoulé milk is completely lacking, except for an estimate made in a village herd in Bouaké of a milk butterfat content of 4.2–5.1 per cent (Glattleider 1976).

(b) ***Somba, Kapsiki, Namchi, and Bakosi***

Kapsiki, Doayo (Namchi), and Bakosi cattle play an important role in the traditional life of the Kapsiki, Namchi, and Bakosi peoples. These animals are neither milked (ILCA 1979b) nor exploited commercially and are used in much the same way as the Muturu cattle in Nigeria for dowry, special feasts, and rituals. The Kapsiki cattle in Cameroon are also associated with burial ceremonies and, like the Muturu in Nigeria, play an important part in complex ritual rites. The Kapsiki are used in some areas as draught animals. Intricate entrustment relations have also been developed among the Kapsiki people to ensure even distribution of the cattle throughout the community (van Beek 1978). However, the role of cattle in religious ceremonies is declining as Islam becomes widespread in the area.

The herd size of Kapsiki cattle is quite variable. Households generally own five to ten heads and, sometimes, fewer (ILCA 1979b). Dineur and Thys (1986) reported an average herd size of 7 ± 2 heads with a range of 2 to 30 heads from a sample of 33 herds. These are brought together in collective herds and tended by children. This herding practice is also employed for the Namchi and Bakosi. At night, animals are kept in pens close to the compound. Reproduction among the Kapsiki is said to be controlled, a practice that has been suggested to be responsible for the maintenance to date of the breed in a relatively pure form (Dineur and Thys 1986).

Bakosi cattle in Cameroon are also neither herded nor milked and are believed to be getting smaller and less fertile as a result of isolation and inbreeding (ILCA 1979b). One animal may have several owners. The few Dwarf Shorthorns in Cameroon—the Bakweri—are kept on palm plantations where they graze the legume *Pueraria phaseoloides* (kudzu), which grows under the palm trees (ILCA 1979b).

Somba is mainly a beef animal kept for social functions (Maule 1990) although it is milked in some areas (Avegan 1984). Because of its small size, however, the Somba is not used for draught. They are usually tended by hired Fulani herders or by children. Herd sizes vary from 10 to 100 animals and can even reach 300 heads. The animals are grazed exclusively on pastures, although traders or functionaries who may own these cattle provide salt-licks, agro-industrial by-products, and crop residues on the pastures (Avegan 1984). In the Somba area in Togo, for example, more than 80 per cent of the residents practise mixed crop–livestock farming. They cultivate food crops, mainly maize, yams, millet, and rice; cash crops, such as cotton, groundnuts, coffee, and cocoa; and horticultural crops, including pineapples, pears, bananas, sugar cane, oranges, and tangerines. Residues from these crops are the main sources of supplementary livestock feed.

Although Togo is not an important livestock country (Somoko-Balantpli and Freitas 1978) and livestock rearing is a minor, almost marginal,

activity, the Kontomba of Central Region and the Kabré of Kara Region, the two major regions of Somba cattle, seem to place more importance on livestock. Husbandry here differs from that of the Fulani in the north. After harvest, animals are allowed to roam freely, unattended, until the next cropping season.

Growth and live weights Birthweights of Somba cattle under village conditions have ranged from 9 to 12 kg for the males and from 7 to 9 kg for the females. These are lower than the average of 21.4 kg reported under station conditions by Grell et al. (1982). The mature weights of the Somba have ranged from 145 to 175 kg for cows, from 200 to 210 kg for bulls, and from 185 to 200 kg for oxen under village conditions. Mature weights varying from 220 to 260 kg have been reported on-station. Mature weights of the Namchi have averaged from 180 to 210 kg for bulls and 150 kg for cows under village conditions. These estimates were based on a rather limited sample of animals and are, therefore, only indicative. Table 3.9 shows the best linear unbiased estimates of live weight, height at withers, and heart girth of limited samples of Namchi and Kapsiki cattle under their natural environments in Cameroon.

Carcass characteristics Information on carcass traits is limited for the Somba and completely lacking for the Kapsiki, Namchi, and Bakosi. Available dressing-out percentages of the Somba have ranged from 48 to 52 per cent under village conditions. These compare well with those of other humpless Shorthorns and Zebus in the region.

Reproductive characteristics Age at first calving under village conditions has averaged 36–48 months for the Somba, 48 months for the Kapsiki, and 36 months for the Namchi, while calving intervals have averaged 12–14 months for the Somba, 18–24 months for the Bakosi, and 12 months for the Namchi under village conditions. Calving interval on-station has been estimated at 15 months for the Kapsiki (Tawah and Mbah 1989). The Namchi appear to mature earlier and have shorter calving intervals than the Kapsiki and the Bakosi in Cameroon. However, Kapsiki's environment is more stressful, both in terms of climate and nutrition, than that of the Namchi. Generally, calving intervals have been much shorter for these breeds than for the other Shorthorns and Zebus in the region, even under village conditions. Calving rates have averaged 60 per cent for the Somba on-station and ranged from 70 per cent on-farm (Dineur et al. 1982) to 84 per cent on-station (Ojong et al. 2021) for the Kapsiki.

In general, most of these breeds have good fertility and, with adequate feeding, calving can occur every year. They have excellent longevity (ILCA 1979b), with the productive lifetime of the Somba estimated to be five to seven lactations (Avegan 1984). Young Somba bulls are sexually mature at 2.5 years of age and remain sexually active for about 12–14 years. However, ILCA (1979b) pointed out that isolation and dwindling populations, with resultant inbreeding, tend to impair the fertility of most of these breeds, especially the Bakosi.

Milk production characteristics Available estimates of milk production in the Somba indicate a range of 1–2 kg of milk per day for 150–180 days of lactation. As with the other breeds, parity influences the lactation milk yields of the Somba. Their lactation milk offtake increased from 176 kg, for a 121-day lactation in the first parity, to 280 kg, for a 152-day lactation in the fourth parity and then declined to 214 kg for a 147-day lactation in the fifth parity. Butterfat content in Somba milk has ranged from 5.5 to 6.5 per cent and is, thus, higher than that of the Ghana Shorthorn and European dairy breeds but comparable to that of the other Shorthorns and Zebus in the region.

Table 3.9 Best linear unbiased estimates of live weight and body measurements of Namchi and Kapsiki cattle under the natural environment in Cameroon

Breed	Sex	Age (years)	N[a]	Live weight (*kg*)	Height at withers (cm)	Heart girth (cm)
Namchi		0–3		158.1 ± 10,4	95.3 ± 1.9	126.2 ± 2.5
		4–7		197.6 ± 5.9	102.9 ± 1.1	138.7 ± 1.4

3.3.3 Other Shorthorn Cattle Breeds of West and Central Africa

Other less known Shorthorn cattle breeds include the ***Manjaca*** and the ***Gambian Dwarf***. A few Manjaca cattle are reportedly found towards the coast in the Cacheu Region of Guinea-Bissau and also on the islands. Da Costa (1933) had earlier described the Manjaca of the Brames Region of the former Portuguese Guinea as '*small, well-proportioned and of typical Shorthorn conformation, distinguished by the black colour of the coat*'. The breed was reportedly disappearing in the 1970s (ILCA 1979b) because of crossing and replacement by other breeds. The subsequent FAO/ILCA studies (Shaw and Hoste 1987; ILCA 1992b), however, made no mention of the Manjaca. This breed has probably been wiped out through interbreeding. In The Gambia, the remnants of the Shorthorns are still found south of the Gambia River, but these populations are being absorbed by the N'Dama, principally owing to the economic superiority of the latter in this environment. Whether purebred or crossed with Zebu, N'Dama is the predominant type in these locations. Equatorial Guinea has about 300 heads of cattle, a small proportion of which are West African Shorthorns of the Savannah type, thought to have originated from the neighbouring Cameroon (Shaw and Hoste 1987). There is a small population of Shorthorns in eastern Chad, known locally as *Taurin de l'Est* (Eastern Taurine).

3.3.4 The Sheko Cattle of Eastern Africa

Classification, Distribution, and Ecological Settings

Sheko cattle are humpless (taurine) cattle of the Shorthorn group. They were first reported in 1929 and later in 1982 in the Shewa Ghimira of the former Kefa region of Ethiopia. They are also referred to as Gida or Mitzan cattle. They inhabit the humid Bench Maji zone in Sheko and Bench districts of the south-western part of Ethiopia, adjacent to the Sudanese border. The Sheko are believed to be the last remnants of the original humpless Shorthorn (*Bos taurus*) cattle in eastern Africa and are the only indigenous humpless cattle found in eastern Africa today. However, although the Sheko are classified as an African taurine breed, a phylogenetic study by Hanotte et al. (2000) showed a high frequency of indicine allele (90%) and low taurine allele frequency (10%) in Sheko males. More recently, Bahbahani et al. (2018) have also reported that the genomes of Sheko cattle are an admixture of Asian Zebu and African taurine ancestries. The same study

suggested that natural selection took place before admixture. The breed is considered to be trypanotolerant with a high potential for dairy production. A small population of these animals that existed in the Nuba Mountains of the Sudan, not far from the present habitat, seems to have been crossed with Zebus.

The Sheko has been traditionally kept by small numbers of local farmers in the warm and humid Sheko and Bench districts under mixed crop–livestock farming systems.

Physical and Adaptive Characteristics

Sheko cattle (Fig. 3.12) have small and compact bodies, without hump or with only small-to-medium-sized hump. They have small horns, but the majority are polled. They have prominent eyes with folded eyelids and a gently sloping rump. Their coat colour is most often brown or multicoloured with black and white. However, brown colour predominates in a plain (75%), patchy (15%), or spotted (9%) pattern. The udders are well-shaped and balanced. Adult height at withers has been reported to be 105 cm, body length to be 102 cm, heart girth to be 136.7 cm, and live weight to be 179 kg (DAGRIS 2022). The breed is well-adapted to live in this environment and produce and reproduce under the tsetse challenge and is known for its milk production and traction capacity.

Production Characteristics

The Sheko is used for milk, meat, and draught. Milk yield is about 2 litres per day, but the persistence is low, and it drops quickly to 1 litre per day in a six-to-eight-month lactation period. Lactation milk yield is 420 litres over an average lactation period of 210 days. The average age at puberty for male and female populations is 41.6 and 42.1 months, respectively, and the average age at first calving is 36–48 months, while the calving interval is 15.6 months, and the average reproductive lifespan of the cow is 14.7 years (Taye et al. 2008) .

To inform the design of genomic breeding programmes, further studies of the breed using a larger sample size with full genome sequence data are needed to confirm the candidate regions under selection that were reported by Bahbahani et al. (2018) to better characterize the underlying haplotypes.

The Sheko is considered endangered mainly because of interbreeding with the neighbouring Zebu and Sanga (specifically the Abigar) and the scarcity of pure Sheko breeding bulls (Takele 2005), which force farmers to use Zebu bulls. Population estimates have been highly variable due to the difficulty in identifying pure Sheko animals. Figures as high as 31,000 heads have been reported. Taye et al. (2008) placed the population of Sheko at only 4040 heads. Moreover, the heterozygosity levels in the Sheko population are lower than expected, and the total number of alleles found in Sheko cattle was the least compared to other contemporary Ethiopian breeds, pointing to high levels of inbreeding in the Sheko breed (Dadi et al. 2008). Molecular genetic evidence has shown that about 90 per cent of Sheko bulls have indicine rather than taurine allele, indicating the extent of introgression of Zebu genes (Hanotte et al. 2000) in the breed.

3.4 Risk Status of Taurine Breeds

As alluded to in Sect. 3.2, of the Taurine Longhorns, the Kuri has a limited ecological habitat—a special environment around Lake Chad where tsetse flies are absent—while the other Taurine Longhorn breed, the N'Dama, and the Shorthorn breeds and strains have evolved in tsetse-infested areas and have developed varying degrees of trypanotolerance. In this regard, the N'Dama is the best-known, the most numerous, and the most widely spread of the trypanotolerant breeds. Population estimates of pure N'Dama cattle across countries in West and Central Africa between 1977 and 1985 have ranged between 7.6 and 9.8 million heads. Thus, this breed is certainly not at risk of extinction.

The Kuri population has previously been estimated at 120,000 in Chad, which hosts about 75% of the breed, and 2350 in Cameroon (DAD-IS: Domestic Animal Diversity Information System 2005). However, based on the meta-analysis of figures in the literature, Rege and Tawah (1999) reported a lower figure of 110,000 for the total population in the Lake Chad

Fig. 3.12 A Sheko cattle herd. (Source: ILRI)

region, covering Chad, Cameroon, and Nigeria. The population of the breed is declining rapidly, with the major drivers being drought, protracted civil conflicts in the region, its inability to thrive outside the lake habitat that is shrinking due to retreating waters of the lake, and extensive crossbreeding with the Zebus that graze on the shores of the lake.

Regarding the Shorthorns, Rege (1999) provided population statistics of the various strains of Shorthorn cattle and their crossbred derivatives (Table 3.10). The table shows that the stabilized crosses—Borgou, Méré, Ghana Sanga, and Keteku—have such large and expanding populations that they are not in any danger. Indeed, they are expanding at the expense of the 'parental breeds', e.g. the Ghana Shorthorn and the Ghanian Dwarf Shorthorn. With an estimated population of only 100–200 heads, the latter is at serious risk of extinction—classified as 'Critical'. The Bakweri (800–1300 head) is also at serious risk, as are the Savannah Shorthorns Bakosi (1000–1300 head), Kapsiki (3000–5000), and, to a lesser extent, Doayo (5000–7500). Among the 'pure' Shorthorns, the Ghana Shorthorn, The Baoulé, and the Somba have the largest populations, while for the 'stabilized' crosses, the Méré, Borgou, and Ghana Sanga have the largest (and increasing) populations. Priority actions for the 'stabilized' crosses include systematic characterization and breed improvement focused on the stabilization of the populations towards distinct breeds or strains. Quantitative data should be collected systematically on their performance relative to that of the parental types.

3.5 Summary and Conclusion

An attempt has been made to collate much of the information presented here from available mainstream and grey literature. However, there are major gaps in knowledge in many of the cattle breeds covered. There is a dire need for up-to-date information, especially comparative data, on many characteristics of African taurine cattle, including their trypanotolerance trait and other adaptive and special genetic attributes. Studies on the relationships between adaptive qualities and production traits in these breeds are particularly limited, as well as comparative breed data on physical characteristics. The reproductive performance of Shorthorns is characterized by late puberty, late maturity, and long calving intervals, resulting in low fecundity rates. However, results obtained in some locations within the region indicate that the improvement of these traits is possible.

Cattle rearing in humid West Africa was nearly impossible in the past owing to the prevalence of trypanosomiasis. However, in recent times, with population pressure, deforestation, crop cultiva-

Table 3.10 Population estimates of Shorthorn cattle types of West and Central Africa

Breed	Synonyms/composition	Approximate population
Savannah Shorthorns		
Ghana Shorthorn	Gold Coast Shorthorn	600,000–800,000
Baoulé[a]	–	745,000–870,000
Savannah Muturu	Muturu	50,000–80,000
Somba	Atacora (Benin), Mango, Konkomba (Togo)	215,000–220,000
Doayo	Namchi, Namshi, Poli	5000–7500
Kapsiki	Kirdi	3000–5000
Bakosi	Bakuri, Kosi	1000–1300
Dwarf Shorthorns		
Lagune	Dahomey, Mayombe (Zaire)	46,000–72,000
Logone	Toupouri	NA
Nigerian Dwarf Muturu	Muturu	25,000–40,000
Ghanaian Dwarf Muturu	Muturu, Forest Shorthorn	100–200
Bakweri	Muturu	800–1300
Liberian Dwarf	Muturu	5000–12,000
'Stabilized' crosses		
Borgou	Zebu × Somba or Lagune	380,000–580,000
Méré	Zebu × Lobi or Baoulé (and N'Dama)	600,000–700,000
Ghana Sanga[b]	Ghana Shorthorn × Zebu	120,000–125,000
Keteku	Muturu × White Fulani, 'Borgu', Kaiama	100,000–300,000
Biu	Dwarf Muturu × White Fulani	NA

tion, and tsetse control measures, the challenge has been reduced. Consequently, there has been an influx of transhumant cattle keepers who visit the zone for dry season grazing and return to the safer sub-humid and semi-arid zones in the wet season. An increasing number of them are settling in the humid zone and are adopting crop–livestock mixed farming. There is also a tendency among some local crop farmers to adopt livestock in the farming systems. Consequently, new (crop–livestock) farming systems are emerging in the zone. The overall impact of these changes has been the increasing interbreeding of the original taurine cattle with Zebus and the emergence of a 'cocktail' of *taurine–indicus* intermediates. This trend is demonstrated, for example, by the changing population of the Muturu cattle: The size of Muturu animals increases as one moves northwards from the deep coastal belt, and this suggests that the animals are being extensively crossed with Zebus and that this practice is more common in tsetse-free areas. Indeed, a review of population estimates from Nigeria in the 1990s already suggested that the Muturu population had declined from about 0.4 million heads in 1960 to somewhere between 50,000 and 80,000 in the late 1980s (ILCA 1992b). This trend is responsible for some reports in the literature that the population of the N'Dama and some Taurine Shorthorns has been increasing (ILCA 1992a).

Owing to their relatively small sizes, the taurine breeds cannot compete with more productive breeds, such as the Zebu, under conditions in which their adaptive attributes do not confer advantage—e.g. under low tsetse challenge. A real effort must be made to improve their performance in traits in which they are weak to exploit their superiority in adaptive attributes. However, their value is in their adaptive attributes, and this is what should underpin their development, conservation, and use, especially for smallholder farmers who are constrained by limited landholdings and limited access to inputs.

4 The History, Geography, and Characteristics of African Zebu, Zebu–Taurine Derivatives, and Well-Established Exotic Cattle Breeds

John E. O. Rege, Chi L. Tawah, Donald R. Kugonza, Mizeck G. G. Chagunda, Isidore Houaga, Oluyinka Opoola, and Eveline M. Ibeagha-Awemu

Abstract

The origins and history of African cattle are covered in the introduction to chapter 3. This chapter covers the African Zebu, Zebu–taurine derivatives, and well-established exotic cattle breeds on the continent. The coverage of breeds is in terms of ecological settings, physical and production characteristics, and adaptive and special genetic characteristics. The African Zebu cattle are classified under the following categories: the Large East African Zebu (LEAZ) and the Small East African Zebu (SEAZ), the Southern African Zebu, and the Shorthorn and the Longhorn Zebu of West and Central Africa. The dominance of the Zebu-type cattle in Eastern Africa and the Horn and the relative absence of distinct Taurine cattle in the sub-region are explained by the two waves of cattle introduction into the continent and their subsequent spread from the point of entry. The other group, the Sanga—breeds and strains derived from interbreeding between African Zebu and Taurine cattle—are found in East and Southern Africa. The 'Sanga' of West Africa are relatively recent, with the process still actively underway and derived breeds still not fully stabilized. They are referred to in this chapter as *'Pseudo-Sanga'*. The chapter also covers another group of breeds known as the Zenga, which are Zebu–Sanga derivatives. These are mainly found in East Africa but also have rep-

resentative breeds in Southern (Mozambique) and Central (the Democratic Republic of the Congo (DRC)) Africa. Also covered in this chapter are the commercial composite breeds developed to combine local adaptation and productivity traits (milk and/or beef) through the incorporation of one or more specialized exotic breeds as sources of the productivity genes. The chapter also summarizes the major well-established exotic cattle breeds on the continent—dairy, beef, and dual-purpose—widely used in crossbreeding for milk and/or beef production. Several Zebu breeds and their derivatives are at risk of extinction, some have become extinct, and many are critically endangered. While no comprehensive analysis of the risk status of African cattle breeds has been done since 1999, it is clear that many more breeds are at escalated risk levels. An updated comprehensive survey is overdue, even as steps are being taken to save the most threatened breeds.

4.1 The Zebu Cattle of Africa

African *Bos indicus* cattle (Zebu), also known as humped cattle, are known to have descended from the introduction of Zebu into Africa from Asia. As presented in detail in Chap. 3, the domestication of the Zebu is thought to have taken place more than 8000 years ago in South Asia, and the centre of origin of Zebu cattle is believed to be India—from where they spread to Africa and south-east Asia.

Zebu cattle are characterized by a fatty hump on their shoulders, drooping ears, and a large dewlap. The Zebu is represented by some 75 breeds in Africa, making it the largest single cattle type (Rege 1999). Approximately 61 of the Zebu breeds in Africa are found in eastern Africa and neighbouring countries in southern–central Africa, while the rest are found in West Africa. Faulkner and Epstein (1957) coined the term 'East African Zebu', to embrace the substantial variation in the morphology of the Shorthorn

Zebu in the region. The term is used today to collectively describe the 'Shorthorn Zebu' of both eastern and southern Africa (Rege and Tawah 1999).

4.1.1 The Zebu of Eastern Africa

Based on body size, the East African Zebu cattle can be further divided into two subgroups—the 'Small' and the 'Large'. The term 'Small East African Zebu' (SEAZ) portrays the small frame of the animals in this subgroup and helps avoid confusion with other types of East African cattle (Mason and Maule 1960). Represented by a total of 49 breeds, the Small East African Zebu (SEAZ) are the majority. The Zebu of eastern and southern Africa are well-adapted to high temperatures and are farmed throughout these regions, both as pure Zebu and as hybrids with Taurine cattle. They are used as draught oxen, as well as for milk and meat production. They also produce by-products such as hides and dung used for fuel and manure.

The Large East African Zebu (LEAZ) is represented by 13 breeds or strains, which are restricted to the relatively drier parts of Sudan, Eritrea, Ethiopia, Somalia, Kenya, Tanzania, and Uganda. The isolations over time that have been imposed by physical/ecological restrictions and/or tribal/cultural boundaries have been responsible for the genetic differentiations that have led to the emergence of different breeds and strains (Rege and Tawah 1999). However, variations in nomenclature associated with different tribes and ecologies do not necessarily imply genetic differences. Thus, breeds or strains that have a common ancestry can be classified further, according to whether they occupy the same geographical area (e.g. a country) and/or a defined ecological zone within one or more countries. Rege and Tawah (1999) referred to these two classifications as clusters and groups, respectively (Table 4.1).

4.1.1.1 The Large East African Shorthorn Zebu

Butana and Kenana Cattle

Origin, distribution, and population statistics: The Butana and Kenana cattle together contribute the larger portion of the 44 million cattle population in Sudan and South Sudan. The rest of the cattle in the area are either Baggara or Nilotic cattle. The Butana cattle breed descended from the first Zebu introduction into Africa. The breed largely remained with nomadic pastoralist tribes (the Batahin and Shukria), especially in the Butana plains in central Sudan, east of Khartoum, in the Butana region—the acacia scrub and desert area lying between the Blue Nile and Atbara rivers. However, some of the Butana strains, for example, the Dongola and Shendi strains, are kept by settled farmers. The breed has spread to Gizera in central Sudan and along River Nile in the northern region. They are referred to as Dar El Reih cattle across the White Nile in the northern part of Darfur and Kordofan.

The Butana is not considered to be at risk of extinction. Their population size was estimated at one million heads in 1994 (DAD-IS 2005). Rege (1999) reported a lower figure of 258,000 based on a compilation of reports of 'pure' Butana over a period ending in 1991. The breed has been subjected to extensive crossbreeding with exotic (European) cattle since the 1950s and has also been exposed to cycles of droughts. Thus, the breed is declining in numbers, and the actual population size is most likely lower than what is available in the literature. Pure breeding of Butana is still practised on-station (e.g. at the Atbara Research Station).

Ecological settings*, management, and production systems:* Butana cattle are kept by the Batahin and Shukria ethnic groups that mainly practise nomadic pastoralism and the Dongola and Shendi ethnic groups that are typical agro-pastoralists. They are kept in the Butana plains of central Sudan between the River Nile tributaries of Atbara and Blue Nile, an area that is arid (Rege and Tawah 1999), receiving about 300 mm of rainfall a year. The Kenana cattle, on the other hand, are reared by semi-nomadic pastoralist Fung and White Nile ethnic groups, mainly in the Blue Nile province that receives between 300 and 800 mm of rainfall in one half of the year, the other being dry entirely (Bahbahani et al. 2018). Overall, the main system of production of Kenana is the range system, which includes the pastoral

and semi-pastoral types. Nomadism in Kenana is relatively mild.

Physical, adaptive, and special genetic characteristics*:* The phenotype of Butana cattle presents a characteristic deep red coat colour, while Kenana cattle phenotypically possess a light blue-grey fur coat that turns from brown-red coat colour in calves up to 6 months of age. Kenana cattle have a shading of nearly black on the head, neck, hump, hindquarters, and legs (Yousif and El-Moula 2006). They have short black horns that rarely grow beyond 30–45 cm, which are relatively shorter in males than in females; loose horns are common. Males possess very large and prominent cervico-thoracic hump and dewlap, just as is typical in other Zebu cattle (Rege et al. 2001).

Like other Zebu cattle, the Butana cattle are known to be superior to the humpless cattle in regulating body temperature—hence, they have lower body water requirements. Their hardened hooves and lighter bones enable them to endure long migrations in their acacia scrub and desert habitat. These adaptive attributes are considered to have facilitated their importation and spread by Indian and Arabian merchants across the Red Sea to the drier agro-ecological regions of the Horn of Africa.

The average cattle herd size among typical smallholder farmers of Butana cattle is six animals, while for Kenana, it is ten animals (Mohammed et al. 2014). Prevalent diseases in the Kenana and Butana cattle-rearing areas include brucellosis, foot and mouth disease, theileriosis, and trypanosomosis. The production environment of the Butana and Kenana cattle is characterized by high temperature, low feed quality and quantity, and a high disease and parasite challenge (Musa et al. 2008). Considering some major production traits, these cattle compare very well with 50% crossbred dairy *Bos taurus* × *B. indicus* cattle in Sudan, as well as with some of the best cattle breeds in other tropical countries (Musa et al. 2008). Breed improvement options that target crossbreeding should ensure that *Bos taurus* genetics are kept to a very moderate level, if at all. The possibility of developing a community-based breeding programme for Butana cattle as a dairy breed focusing on optimizing milk yield, growth performance, and lactation length is real, considering that over 66% of farmers who rear these cattle are willing to exchange breeding bulls and establish farmers' associations (Omer et al. 2021). At the mitochondrial DNA (mtDNA) level, only taurine mtDNA sequences have been identified, with high diversity (Salim et al. 2014).

Production characteristics: Butana cattle have typical dairy characteristics with an established history of active selection for milk production. Although the breed is raised as a dual-purpose breed, it is known for its good milk production in its harsh habitat. Milk yield per lactation ranges from 1200 to 1800 kg in an average lactation of 240 days. Under on-farm conditions, the average milk offtake is 1.5 kg per cow per day for durations often exceeding a year, and the milk is consumed fresh or used to make ghee and butter, as the milk butterfat content is quite high (4.5% for Butana and 5.5% for Kenana cattle) (Rege and Tawah 1999). Under on-station conditions, their production averages 1662 kg for Butana in a 268-day lactation length (Musa et al. 2005, 2006) and 2264 ± 131 litres in a mean lactation length of 283 ± 11 days (Medani 2003). For the same conditions, the Kenana cattle breed has a mean yield of 1400–2100 kg for a 198–257-day lactation (Musa et al. 2005, 2006) and 1836 ± 186 litres in a mean lactation length of 308 ± 6 days (Medani 2003). Contemporary characterization studies, however, reported that the productive performance of Butana and Kenana cattle is similar at an average of 1415 kg of milk per lactation of 251 days (Lutfi et al. 2005), with a maximum record for an individual cow of 4530 kg in a lactation (Saeed et al. 1987). An average lactation yield of 3626.7 kg has been reported in a meta-analysis (DAGRIS 2022). These characteristics lend to the classification of these cattle as Africa's indigenous Zebu-type dairy cattle. An assessment of the environmental and genetic factors affecting the milk production of the Butana cattle based on single-record milk yield on-station reported a heritability of 0.278 ± 0.232 and a repeatability of 0.415 ± 0.037 for milk yield (Alim 1962).

Ageeb and Hillers (1991) (Yousif and El-Moula 2006; Wilson 2018) have reported some growth and reproduction parameters. Age at first calving in Kenana cattle averages 4.5 years under traditional production systems, but under improved management, it reduces to 3.0–3.5 years (Wilson 2018). The average birthweight of Kenana cattle is 22.7 kg (range 21–26 kg in males and 20–24 kg in females), rising to 56.7 kg at 6 months and adult bulls and cows attaining 300–500 kg (average 370 kg) and 250–350 kg (average 320 kg), respectively. Calving intervals measured on-station averaged 18 months with a lifetime production of 4.02 calves (mean) and 12 calves (maximum), while on-farm, under traditional systems, cows are culled after three calvings, with an average lifetime production of 2.9 calves (Wilson 2018). Earlier studies had reported a mean calving interval of 416 days (13.8 months) (Alim 1962). The rather low production level on-farm could be partly explained by the high age at first calving. Repeatability for calving interval has been estimated at 0.111 ± 0.039, 0.415 ± 0.043 for lactation period, and 0.221 ± 0.037 for dry periods. The average calving rate was 59%, measured over four decades ago, and was distinctly higher (60%) in migratory than in sedentary (40%) production systems.

The two breeds (Butana and Kenana) produce an estimated 7.4 million tons of milk annually (Wilson 2018). They also contribute an estimated 67.2% of red meat. Butana cattle additionally provide draught power and insurance and meet the sociocultural needs of the rural communities that rear the breed (Omer et al. 2021).

Figure 4.1 presents a Butana cow with a calf and a Kenana cow.

Baggara Cattle

Distribution and population statistics: Like their neighbours, Butana and Kenana, the Baggara cattle descended from the first Zebu introduction into Africa. The Baggara are reared in the west, central, and southern Darfur; central and southern Kordofan; Nuba Mountains; and the Sulien Baggara sub-region of Sudan. They are named after the Baggara people of western Sudan and central Chad, who raise these cattle. *Baggara* means cattle people in the local Shuwa Arabic language. Baggara cattle have common grazing lands and migratory routes with small Nilotic and large Fulani cattle, which results in indiscriminate crossbreeding, leading to admixture, with unknown breed composition and high variability in body conformations. Baggara cattle are estimated to constitute 33% of the total 44 million national cattle herd of Sudan.

Physical characteristics: They are medium-sized, smaller, and thinner than the Boran breed of Kenya and Ethiopia and have varied coat colours, horn shapes, and conformation. They have cervico-thoracic humps, which are relatively large, particularly in males, and their dewlaps are well-developed and prominent. The cattle in Darfur possess the largest horns. Baggara cattle are smaller than the Boran breed of Kenya and Ethiopia. Baggara cattle are horned with cervico-thoracic humps and have a large and prominent dewlap. Figure 4.2 shows a herd of Baggara cattle.

Production characteristics and uses*:* The breed is primarily used for beef and is the major beef animal in Sudan. Baggara cows typically produce 1.2–2.5 kg of milk per day, with a total 305-day adjusted lactation milk yield of 366 kg. Under favourable conditions and good management, 70% of the cows become pregnant, compared to 45% of cows under unfavourable conditions. About 25% of the cows that conceive normally fail to maintain the foetus to full term and abort, usually towards the end of the pregnancy period. Malnutrition, arising from substantial seasonal feed shortages, and stresses from diseases have been suggested as the main causes of foetal loss. There have been concerted breed improvement programmes of the Baggara by the Sudanese Department of Agriculture.

Adaptive characteristics: The Baggara are characterized by their adaptive characteristics and high performance in hot and dry agro-ecosystems such as in the dry Sahel. The related Butana and Kenana breeds of the Nile Valley, known for their good dairy attributes, need much more feed and water than the Baggara.

The Karamojong Zebu

Distribution and population statistics: The Karamojong cattle is the only LEAZ type found in Uganda. They were estimated to be 510,000 heads in 1999, and the population has most likely increased (even doubled) with the control of cattle rustling and increased livestock management infrastructure in the Karamoja region, animal disease management, the establishment of livestock water reservoirs, and pasture improvement efforts. These cattle are kept by the Jie, Pian, Matheniko, Tepeth, Dodoth, Nyaakwae, Bakora, and Pokot tribes, who are collectively classified as the Karamojong people, numbering about 1.2 m people (UBOS., The Uganda Demographic and Health Survey (UDHS), Uganda Bureau of Statistics (UBOS) 2011), and are nomadic pastoralists who roam large areas in search of water and pasture for their livestock. They occupy the entire North-Eastern region of the Republic of Uganda, incorporating the districts of Abim, Amudat, Kaabong, Karenga, Kotido, Moroto, Nabilatuk, Nakapiripirit, and Napak, an area of 27,900 square kilometres (Loquang 2003).

Ecological settings*, utility, and management:* The Karamojong tribe that maintains this breed is the most influential tribe among the Karamoja-Nilotic people in the north-eastern region of Uganda, and their herds are maintained in the original homeland. These cattle are kept for their multipurpose roles that include the provision of milk, meat, and blood (all used as food); payment of dowry; the provision of hides that are used for shelter, beddings, and making of traditional sandals; the provision of dung that is used for building homesteads and as manure; and the use as a source of power for cultivation, transport, and haulage (Loquang 2003). The skin of calves is used as clothing, though this practice is slowly dying out.

Physical, adaptive, and special genetic characteristics: Karamojong cattle are a large breed with coat colours varying from red, light fawn, or tan (with or without white patching), roan, grey to white. Their horns vary widely in length and shape, and they possess a large and dome-shaped hump. The dewlap, umbilical fold, and sheath are larger in the Karamojong type than in the Toposa, and their udder is moderately well-developed. The cattle are similar in conformation to the Boran cattle—deep body, long legs, and well-developed pyramidal hump. Figure 4.3 shows typical Karamojong cows.

The Karamojong cattle have several unique characteristics that include being drought-tolerant, disease-resistant, and generally a 'hardy breed'—e.g. they do not require a lot of forage, can survive for many days without drinking water, and can easily graze on rough terrain. In addition, their meat is considered tastier and more tender than that of the other cattle breeds in the area. The cattle-keeping community practises selective breeding with particular focus on the breeding of cows and bulls that are hardy and can trek for long distances in search of pasture and water, are aggressive and can ward off predator attack, are disease-tolerant, and do not experience calving difficulty (Rege and Tawah 1999). Selective breeding is made possible by applying strict selection criteria that target animals of well-known lineage, with parents known to perform well, from a lineage of animals that are disease-tolerant, and with offspring that remain healthy right from birth to maturity. Consequently, these cattle are well-adapted to their very dry climate and semi-nomadic pastoral system.

Production characteristics: Karamojong cattle are largely reared for milk and meat (Rege 1999). In addition, they are used for ploughing. The mature live weight of these cattle is 320–490 kg in males and 300–410 kg in females. A study by Behnke and Arasio (2019) reported that the cattle in Karamoja make very substantial economic contributions to Uganda's national livestock economy—accounting for 39% of the national cow milk value and 27% of the national cattle offtake value.

The Boran/Borana Cattle

Origin, distribution, classification, and population statistics: The Boran is a Zebu breed maintained by the Borana pastoralists of southern Ethiopia and contiguous areas of Kenya and Somalia. It is considered that all the Boran cattle were derived from the native Shorthorn Zebu cattle of the cattle-

Fig. 4.3 Typical Karamojong cows with suckling calves. (Courtesy: Dr. Donald Kugonza)

keeping tribes of southern Ethiopia—home of the Borana people. It is estimated that their ancestors arrived in the Horn of Africa about 1300–1500 years ago from south-west Asia. Large numbers of these animals then migrated from the Liben Plateau of southern Ethiopia to Somalia, where they are named as the Awai cattle, and to Kenya, where they are known as the Tanaland Boran and Orma Boran. In the 1920s, European ranchers in Kenya purchased the Tanaland Boran cattle and, through selection, developed the Improved Boran. The present-day Boran cattle populations in eastern Africa can be classified under five strains (Rege 1999): Ethiopian Boran (Borana), Unimproved Boran (Boran), Orma Boran, Somali Boran (Awai), and the Improved or Kenya Boran (commercial breed).

Today, the Ethiopian Boran (Borana) cattle are mainly found on the Borana Plateau, from the Liban Plateau to the extreme south, where they number about 1,896,000 heads. The Improved Boran is essentially a commercial breed kept in the commercial ranches in Kenya, has been selected for beef production, has 580,570 animals, and has been exported to Tanzania, Uganda, the Democratic Republic of Congo (DRC), and Zambia. Over time, the development of the Improved Boran has incorporated the Orma Boran, the Borana of Ethiopia, and the Somali Boran. The Kenyan Boran Cattle Breeders' Society has been in existence since the early 1950s and has been spearheading the selective breeding of the Boran in the country. In more recent times, the Boran breed was introduced to Australia, the United States, Brazil, and Mexico. As of 2008, there were approximately 454 beef ranches in Kenya, under five categories: group ranches, private company ranches, cooperative ranches, public company ranches, and government ranches. The Boran breed is a common feature across these ranch categories in Kenya.

The Kenyan Unimproved Boran cattle are kept in north-east Kenya, where there are 1,882,000 animals, largely owned by pastoral herders, while the Orma Boran cattle breed is kept in the North-east of Kenya, with a total of 547,000 heads.

Ecological settings*, management, and production systems*: The habitat of the Borana or Boran cattle in Ethiopia, Kenya, and Somalia is typically the arid and semi-arid lands characterized by recurrent drought, degraded rangelands, and an increasing reduction in access to traditional grazing lands. The region has a savannah landscape, marked by gently sloping lowlands and floodplains vegetated predominantly with grass and bush land. Pasture is the main (and often the only) source of feed for livestock in these pastoral systems. Severe grazing shortage is common. Severe livestock losses and reduced livestock productivity are also common during dry periods. This situation is being exacerbated by climate change and invasive weeds such as *Ipomoea* spp., *Prosopis* spp., and *Parthenium* spp., which are also accelerating the degradation of the rangeland ecosystem in these areas.

Annual mean temperatures in the Boran habitat vary between 19 and 24 °C. Rainfall in the Borana lowlands is bimodal, with long rains expected between March and May (59% of the rainfall) and short rains (27%) between October and November, but these have changed significantly recently. Mean annual rainfall between the years 1988 and 2001 was 412–566 mm. The scarcity of surface water is widespread, and livestock are trekked long distances in search of both water and pasture. Over the past three decades, there has been an increasing incidence of recurrent droughts, reduced rainfall, and a decreasing availability of grazing and water resources. However, the feed situation is significantly better on the ranches—typically with improved pastures, fodder crops, and other supplementary feeds, as well as water sources. The woodlands of Borana rangelands are characterized by species from the genera *Combretum* and *Terminalia*, whereas the bushlands and thickets, which cover major parts of the Borana lowlands, are dominated by *Acacia* and *Commiphora* species. Pastures are predominantly short-lived perennial or annual grasses with scattered eucalyptus trees. They occur on level-to-undulating plains. Soils are variable-depth loams, sometimes calcareous, and the surface may be stony.

Physical, adaptive, and special genetic characteristics*:* The Boran cattle breed has the ability to survive, produce, and reproduce under high ambient temperatures, low-quality forage resources, long watering intervals, and tick infestation. As such, the breed is versatile and well-adapted to arid and semi-arid environments. Boran cows are efficient converters of pasture forage into body fat deposits, which are mobilized during periods of feed scarcity and lactation, minimizing the loss of body condition during lactation or slight droughts (Hagos 2016).

A phylogenetic study (Hanotte et al. 2000) indicated that the Boran has a 100% indicine Y allele. However, a subsequent study (Hanotte et al. 2003) analyzed the autosomal loci of the Boran and reported the proportions as 64% *Bos indicus*, 24% European *Bos taurus,* and 12% African *Bos taurus.* The European-Near East taurine background in the Boran is of some antiquity and possibly recent crossbreeding with exotic European taurine, as well as an African indigenous taurine background, which is not found in any Asian Zebu crosses such as Sahiwal or Brahman.

The Ethiopian Borana is a medium-sized, deep-chested, and long-legged cattle breed. Its coat colour is white, light grey, or fawn with black or dark brown shading on the neck, head, shoulders, and hindquarters (Rege et al. 2001). Its horns are thick at the base, short and erect; the hump is well-developed and hangs over to one side in males, as is typical of Boran cattle, and cows have well-built udders. The Kenyan Improved Boran, on the other hand, possesses a white coat colour with black spots and resembles other types of Boran but mainly differs from the Unimproved Boran by having a straight top line and well-developed hindquarters. Ethiopian Borana may also have other colours ranging from brown to red, though these are rare in occurrence. The breed is medium in size with a short head, small ears, loose dewlap, and a large hump above the shoulders. They can be horned or polled. They vary in height at the withers from 114 cm to 147 cm. Their skin is loose, thick, and extremely pliable—an attribute that is linked to enhanced insect repellence. The skin is also dark-pigmented with fine, short hair, which is considered to provide heat tolerance.

The Orma Boran cattle typically have a white or fawn coat colour with unpigmented skin. It is mostly used for milk and meat. The Orma are well-adapted to local conditions and parasites. They are also known for their fertility, early maturation (compared to other Zebu breeds), hardiness, and docility. Studies have indicated that the Orma Boran may have a degree of resistance to African trypanosomosis and can be productive under tsetse challenge with minimum drug intervention (Dolan 1997; Bett et al. 2004). Figure 4.4 presents a Kenya Boran bull (a) and herd (b) in a ranch and Ethiopian Boran bulls (c).

A recent review (Bayssa et al. 2021) has attributed a higher resistance to biting insects and tick infestation in the Boran to the following attributes of the breed: (a) a highly sensitive and motile skin with a thick, well-developed

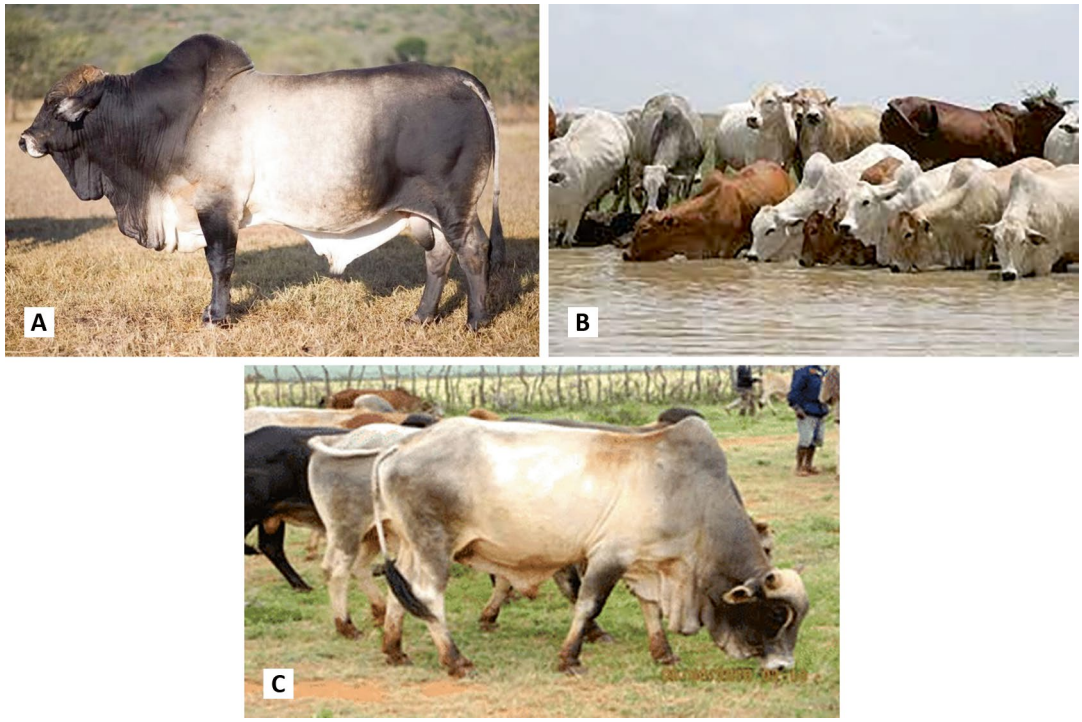

Fig. 4.4 A Boran bull (**a**) and herd (**b**) at the Sosian ranch in Kenya and typical Ethiopian Boran bulls in Yabello, Borana, southern Ethiopia. (Courtesy: ILRI)

layer of subcutaneous tissue, which causes the muscles beneath the skin to contract and move in reaction to insects—thus enabling them to shake off external pests; (b) short hair coat, which makes it difficult for insects to attach onto the hides of the Boran cattle; (c) a waxy and oily secretion from the skins of the Boran, which makes them less desirable hosts for ticks and flies; and (d) prominent, protective eyebrows and long eyelashes, which protect their eyes from bright sunlight, dust, and other irritants that predispose cattle to pinkeye infection. Other studies have attributed the ability of the Boran to thrive well in hot and dry environments to the high number of sweat glands, which allow it to withstand high ambient temperatures (DAGRIS 2022).

Production characteristics: Boran cattle are used mainly for milk and meat. The Improved Boran is primarily reared for meat, milk, and work (Rege et al. 2001), but the breeding focus is on beef traits. The average birthweight of the Ethiopian Boran is 25 kg for male calves and 23 kg for females, while weight at maturity is 300–385 kg (male) and 300–350 kg (females). The Improved Kenyan Boran differs from other Boran sub-types due to its larger size and well-developed hindquarters. The prominent sizes of the Kenyan Improved Boran make them the heaviest in the region, at 550–850 kg in mature males and 400–550 kg in mature females. The Kenyan Unimproved Boran is much smaller than the Improved Boran and attains a mature weight of 255–395 kg (males) and 250–355 kg (females). The mature males of the Somali Boran weigh 295–410 kg, and females weigh 230–355 kg, while the male Orma Boran range in size from 225 to 395 kg and the females from 250 to 355 kg. Besides the well-developed beef conformation, the Boran also exhibits good carcass quality characteristics: The depth of eye muscle, marbling, an even fat cover, and the ratio of hind to forequarter stand out in the Boran compared to other local breeds and make well-finished Boran steers the favourites of butchers and hoteliers in Kenya.

The Improved Boran cows have been reported to produce 1130 kg of milk over a 36-week lactation period, with calves suckled three times a day (DAGRIS 2022). Under a more favourable production environment, Boran cows produce up to 1657 kg of milk over a 252-day lactation period (Zander et al. 2009). Overall, although their production potential is less compared with exotic and crossbreeds, the level of production of Boran cattle is relatively stable during harsh conditions where high-producing exotic animals are at risk (Abdurehman 2019).

4.1.1.2 The Small East African Shorthorn Zebu

The Small East African Zebu (SEAZ) is the main type of cattle populating East Africa (Rege et al. 2001). The SEAZ are preferred by the majority of local smallholder farmers over the pure exotic highly productive taurine breeds due to their superior adaptability to the local environment, which is characterized by a warm climate (20–23 °C), high humidity (60–80%), and high disease challenges (e.g. *Theileria parva, Ehrlichia ruminantium*, and *Haemonchus placei*) (de Clare Bronsvoort et al. 2013). These cattle show a degree of resistance to *Rhipicephalus appendiculatus* tick and the vector of East Coast fever (ECF) protozoan parasite *T. parva* (Latif et al. 1991; Latif and Pegram 1992) as well as tolerance to poor forage and water scarcity (Western and Finch 1986). A mortality rate of 16% has been observed in an SEAZ population of western Kenya under the traditional management system (de Clare Bronsvoort et al. 2013; Thumbi et al. 2013). The mortality was mainly attributed to ECF, haemonchosis, and heartwater.

The genetic structure of these cattle has been investigated by Mbole-Kariuki et al. (2014) using mid-density genome-wide single nucleotide polymorphism (SNP) data. The study confirmed the long-held position by many researchers that the East African Shorthorn Zebu (EASZ) is a stabilized admixed population of Zebu and African taurine ancestries. The average genome proportions reported by this study were 0.84 ± 0.009 and 0.16 ± 0.009, respectively. However, some of the EASZ animals showed recent European taurine introgression, likely linked to artificial insemination programmes aiming to improve indigenous cattle productivity (Mbole-Kariuki et al. 2014). This crossing with European taurine cattle has been linked to the increased vulnerability of EASZ to infectious diseases (Murray et al. 2013).

A recent high-density genome-wide SNP analysis of the EASZ from Kenya (KEASZ) and Zebu × Taurine–admixed cattle populations from Uganda and Nigeria (Bahbahani et al. 2017) found that 25 of the regions were shared between KEASZ and Uganda cattle, and seven regions were shared across the KEASZ, Ugandan, and Nigerian cattle. The identification of common candidate regions allowed the mapping of 18 regions that intersect with genes and quantitative trait loci (QTLs) associated with reproduction and environmental stress (immunity and heat stress) and was interpreted to suggest that the genomes of the Zebu × Taurine–admixed cattle have been uniquely selected to maximize the hybrid vigour, in terms of both reproduction and survivability.

The ***Teso Zebu*** group of Uganda consists of two strains, the *Kyoga* and the *Usuk*. The Kyoga inhabits the Lango and Kaberamaido areas, is larger than the Nkedi, and has deeper chest and shorter legs. The forehead is broad, and ears are pendulous. The Usuk is found around the north-east and North Teso areas adjacent to the Karamoja and is also larger than the Nkedi (Rege and Tawah 1999). The Nkedi cattle occupy Bukedi, Lango, and much of South-Eastern Uganda (Pallisa, Iganga, Kamuli, and Tororo areas). In Kenya, the Teso Zebu is reared by the Teso ethnic group in the Busia district of Western Kenya, near the border with Uganda.

The ***Highland Zebu*** cattle of Kenya (also known as Kikuyu Zebu) occupy the highlands of central Kenya, where they have been heavily crossed with purebred exotic European breeds. The breed is currently endangered. The ***Lowland or Coastal Zebu***, on the other hand, include four strains named according to the tribes that keep them, namely Kamba, Taita-Taveta, Giriama, and Duruma. The Maasai Zebu have their homeland

in Southern Kenya and the adjoining areas of northern Tanzania, particularly in the Moshi, Upase, and Usambara areas. Due to the centuries-old traditional practice of cattle raids, present-day cattle of the Maasai are very heterogeneous, having some similarities with the adjacent Kenyan Zebu breeds (Rege and Tawah 1999). In Tanzania, the Maasai Zebu is found distributed from the northern to the southern parts of the country. Genetically, Maasai cattle are clustered with the Nandi, Taveta, Turkana, and Teso Zebu cattle (Rege et al. 2001).

The ***Kavirondo Zebu*** are kept by the Luo and Luhya ethnic groups that occupy the Nyanza and Western provinces/regions of Kenya in the Lake Victoria Basin. A small cluster of SEAZ cattle called the ***Lugware*** includes ecotypes called the Bahu, Lagware, and Lugwaret. The Lugware ecotypes are kept in the Democratic Republic of Congo in the Kibali-Ituri district, in the north-western part of Uganda, west of River Nile.

The Tanganyika Shorthorn group is made of the ***Iringa Red*** that is reared in the Singida region of Central Tanzania and the ***Maasai Grey*** that thrives in Moshi, Upase, and Usambara regions of Northern Tanzania. The ***Ugogo Grey***, ***Mkalama Dun***, ***Singida White***, and ***Pare*** cattle occupy central Tanzania, while the ***Tarime*** and ***Chagga*** are in the Mara and Usambara regions, respectively.

Ecological settings*, utility, management, and production systems*: Poor nutrition is one of the major problems affecting livestock productivity in the habitats of the Zebu cattle. This is normally reflected in reduced live weights, perpetual low animal productivity, late age at first parturition, increased parturition intervals, prolonged non-productive life, and high mortalities. The production systems in most habitats of the SEAZ are typified by natural pastures as the major feed resource, and its utilization is through continuous grazing.

Tethering is common during the cropping season in some locations—e.g. in Kitui County of Kenya. This system is often adopted in response to the shortage of herding labour when farming activities are at their peak. Tethered animals can obtain sufficient access to pasture during this period of the year while also ensuring control of animals that could otherwise stray onto other people's farms. Feed conservation is commonly practised in the form of crop residues (cereal straws) and hay from native pastures. These conserved feeds are fed to animals during the dry season, work oxen during the cropping season, and in-calf and lactating cows. Supplementation of the indigenous breeds using high energy and protein concentrates is rarely practised in these systems. Equally rare is the provision of mineral licks as part of cattle diets. However, animals exploit various natural salt deposits that exist in the grazing fields. These practices are similar to those prevalent in other regions of Africa—e.g. in Nigeria (Pullan 1979; de Jode et al. 1992) and Botswana (Trail et al. 1977).

Physical, adaptive, and special genetic characteristics*:* The typical SEAZ is a relatively small, dual-purpose animal and is stocky in appearance. They have no dominant coat colour, but black, black and white, brown, brown and white, and a 'dalmatian' pattern are common. The horns are short and thick at the base and curve slightly outwards. The musculo-fatty hump is prominent and thoracic in position. The ears are medium-sized and directed outwards. The skin is of medium thickness, and the hair is short and smooth. The hooves are medium and hard. Horns are short and lyre-shaped, and the hump is well-developed with a varying posterior overhang. The dewlap is of moderate size. The Lowland Zebu varies in coat colour from black to red, and there are significant variations in horn shape, horn presence, and hump size. The Lugware are small-sized, hardy, and fine-boned, with coat colours varying from black to grey and from brown to white. Their skin is pigmented, and the horns are short and grow sideways and upwards in a crescent shape, while the hump is large, as is typical of Zebu cattle, and tends to hang over to one side at the rear. The dewlap is moderate in size, and the umbilical fold is very small. Figure 4.5 shows an SEASZ in Tanzania.

Production characteristics. The Taita-Taveta Zebu weight ranges are 194–405 kg in mature males and 125–360 kg in mature females (Rege et al. 2001). The bodyweights of the adult Maasai

Fig. 4.5 A herd of Small East African Zebu in Tanzania. (Courtesy: Dr. Gladness Mwanga)

Zebu range between 300 and 445 kg in mature males and between 275 and 385 kg in mature females. The Kavirondo Zebu cattle have a black coat colour, though white and a combination of both are also seen. The mature weights of these cattle are 215–419 kg (males) and 195–365 kg (Females) (Rege et al. 2001). Mwacharo and Rege (2002) reported average milk production per day of 1.6 litres in Kenya, with significant differences being observed between locations (counties) and, hence, Zebu strains, at the start and peak of lactation.

4.1.2 The Southern African Zebu

The Zebu breeds of southern Africa are in two groups, ***the Angoni group*** and the ***Madagascar group***. The former includes *Angoni (*of Zambia*)*; *Angonia* or *Angone* (Mozambique); and ***Malawi Zebu,*** while the latter has two breeds, the ***Baria*** and the ***Madagascar Zebu***. A brief description of these breeds is presented below.

The Angoni

Distribution and ecological settings*:* The Angoni belongs to an SEAZ group of cattle believed to have been introduced to Africa by the Indian and Arabian merchants. The Angoni group of cattle is believed to be the descendant of the original Zebu introduced through the Horn of Africa. These cattle were maintained by the Angoni people who descended from the Nguni tribe in South Africa. The Angoni people are supposed to have lost their original Sanga cattle and restored them with Zebu as they wandered as far north as Lake Tanganyika and subsequently settled on the Angoni plateau of eastern Zambia and the adjoining parts of Malawi between 1850 and 1870. These cattle became known as Angoni cattle. The Angoni people later spread southwards, reaching north-western Mozambique. The cattle breeds that emerged in this process are known today as *Malawi Zebu* in Malawi, *Angoni* in Zambia, and *Angone* or *Angonia* in Mozambique (Rege and Tawah 1999). Angoni cattle are mostly found in the Eastern province of Zambia, parts of Isoka district in Muchinga province, the adjoining areas of Malawi between the Lungwa River in the west and Lake Malawi in the east, and into Tanzania. They also spread southwards, reaching north-western Mozambique. In Mozambique, they are distributed north of the Zambezi River, in the plateau of Tete in the Tete district, in a small area of Angonia to the extreme north-east on the Malawi border.

Physical and production characteristics *and* uses*:* The coat colour of the Angoni in Zambia is highly variable—red, brown, black, red or black and white, or brindle. Similar to Malawi Zebu,

the horns of the Zambian Angoni are short and thick and lateral rather than upright. The hump and dewlap are well-developed. The Angoni has a compact body frame that is generally larger than the Tonga but smaller than the Barotse. The body size varies from medium to large, with males weighing up to 730 kg. The Mozambique *Angone* is much smaller than the Zambian Angoni and resembles the Malawi Zebu more than it does the Zambian Angoni. The large size of males and the large compact body make them ideal for draught power. Nearly all the males and, in some instances, even females are used as work animals. The females have characteristic large udders that make the breed ideal for crossing with exotic breeds for milk production. Typical Angoni bull and cow are shown in Fig. 4.6.

With an estimated population of 797,000 heads in Malawi, 300,000 in Zambia, and 65,000 in Mozambique, the Angoni is not yet at risk. However, its continued interbreeding with neighbouring Sanga populations may put it at risk over time.

The Madagascar Zebu

Distribution and ecological settings: The *Madagascar Zebu*, also called *Omby Malagasy*, is believed to have originated from the interbreeding of the Indo-Pakistani Zebu cattle and the African Sanga cattle. Indonesian immigrants are known to have brought Indo-Pakistani Zebus to Madagascar from India and Arabia, while Hamitic and Bantu people from East Africa introduced humpless and Sanga cattle. East African Zebus were also imported to the island from 1506 onwards, and the interbreeding among these cattle produced a stabilized indigenous breed of the Madagascar Zebu today (Rege and Tawah 1999). More recent studies have found a higher indicine ancestry in the Madagascar Zebu populations as compared to other African continental Zebus and have attributed this to a second pulse of Indian Zebu introgression into an already admixed African taurine × Zebu population of likely East African origin that traces back to the twelfth century (Hanotte 2002; Magnier et al. 2021).

Physical characteristics: The animals have thoracic humps and are short-horned. The hump is large and pyramidal. Some animals, especially in the west of the island, do have long horns. The coat colour of the Madagascar Zebu cattle is very much a result of active selection by different tribes for particular colours and patterns. Indeed, there are 140 words in the Malagasy language that describe these variations (Felius 1995).

Adaptive and special genetic characteristics: Madagascar Zebu is considered to be well-adapted to the conditions on the islands where it is found. In particular, they are generally regarded as more resistant to heat stress and tick-borne diseases than imported European breeds, such as African Zebu and N'Dama breeds.

The Malawi Zebu

The Malawi Zebu are found throughout Malawi and are the dominant cattle breed in Malawi, con-

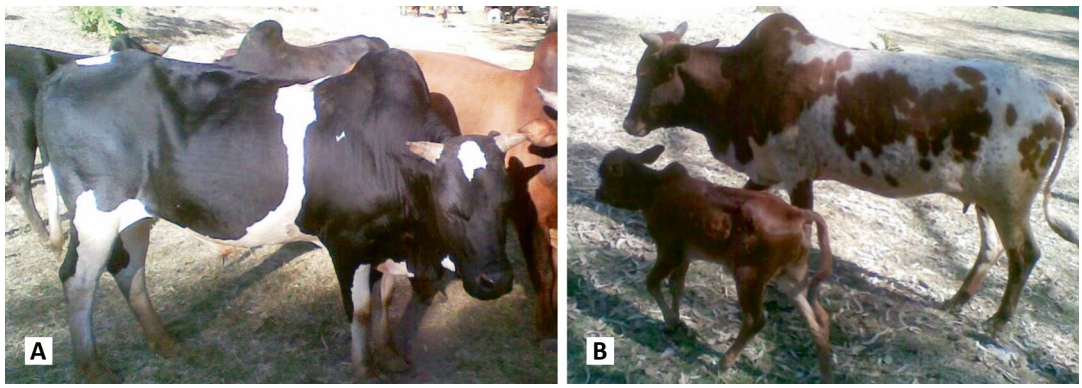

Fig. 4.6 Angoni bull (**a**) and a cow with a calf (**b**). (Courtesy: Dr. Maria da Gloria Taela)

stituting the largest proportion of the 800,000-strong national cattle herd. They are generally similar to the Angoni of Zambia. However, because its hump is more cervicothoracic and it has larger ears and less developed dewlap (similar to the Nguni), it is considered to have some Sanga blood, from the opportunistic interbreeding with the Nguni Sanga inhabiting the same area. Consequently, the populations in central and southern Malawi are slightly different in conformation from the other Angoni. This has led to the classification of the Malawi Zebu into *North Malawi Angoni* and *South Malawi Angoni* (Felius 1995).

Herds of Madagascar and Malawi Zebu breeds are shown in Fig. 4.7a, b, respectively.

Baria Cattle

The Baria cattle are found in the western region of Madagascar in the Plateau de Bemaraha. It is a small, wild, and free-roaming population. They have not been sufficiently characterized, and their origin is uncertain. They have been referred to in different reports as Sanga, Zebu, and Taurine. However, the Madagascar official reports consistently classify the Baria as Zebu. Their limited use and neglect have caused a decline in the population of the breed. With a population estimated at about 500, the breed is considered critically endangered (Rege 1999).

4.1.3 West and Central African Zebu

Most of the West and Central African Zebu cattle are reared in the Sahel belt, which serves as a geographic and ecoclimatic bridge between the Sahel and the Savannah and Forest belts (Ouedraogo et al. 2021). They have historically inhabited the dry savannah and Sahelian zones, while the taurine (humpless) breeds have been widely distributed across the moist savannah and sub-humid coastal forest belts (Rege and Tawah 1999). The latter zones are infested with tsetse flies, which are the vectors of Nagana or trypanosomosis in cattle. However, the distribution of these populations has been shifting towards the coastal belt because of frequent droughts and insecurity in the Sahel. Consequently, many pastoralists have migrated with their animals into the humid and sub-humid areas (Boutrais 2007; Traore et al. 2015) where their animals have interbred with the humpless cattle. This crossbreeding between the *Bos taurus* and *Bos indicus* cattle has resulted in a new group called the West African (*Pseudo*) Sanga cattle (e.g. Borgou, Djakore, Ketekou, Ghana Sanga, and Pabli) (Sect. 4.2.3).

Rege (1999) classified the West and Central African Zebu cattle into the Gudali (represented by the Adamawa, Sokoto, and Ngaoundere Gudali) and the Fulani (represented by the lyre-shaped White Fulani and the long lyre-shaped Red M'bororo types, the Awazak, the Shuwa, and the Maure). Table 4.2 summarizes the West and Central African Zebu cattle breeds.

The Zebu of West and Central Africa are raised in a range of production systems—from on-station (intensive, mostly research stations) and ranches (public or privately owned) to the majority, which are on-farm mostly extensive, including pastoral and agropastoral production systems. The extensive system is dominant and primarily comprises smallholder producers with indigenous cattle as their dominant stock because of their adaptability to the prevailing ecological conditions. These animals contribute to the economies of this sub-region in significant ways in terms of food, income, employment, culture, and ecosystem stability. The two types, Shorthorns and Longhorns, are described in the sections below.

4.1.3.1 West and Central African Shorthorn Zebu Cattle

The West and Central African Shorthorn Zebus are similar in origin, physical appearance, and conformation to the East African and Indo-Pakistan Shorthorn Zebus (Payne 1970). They are classified as being among the Sahelian Zebu breeds that are believed to have descended from the Indo-Pakistan Zebu, which entered the Horn of Africa by way of the Persian Gulf and south Arabia. The Arabian invaders spread the Zebu to the south and west over the continent from 669 BC (DAGRIS 2022).

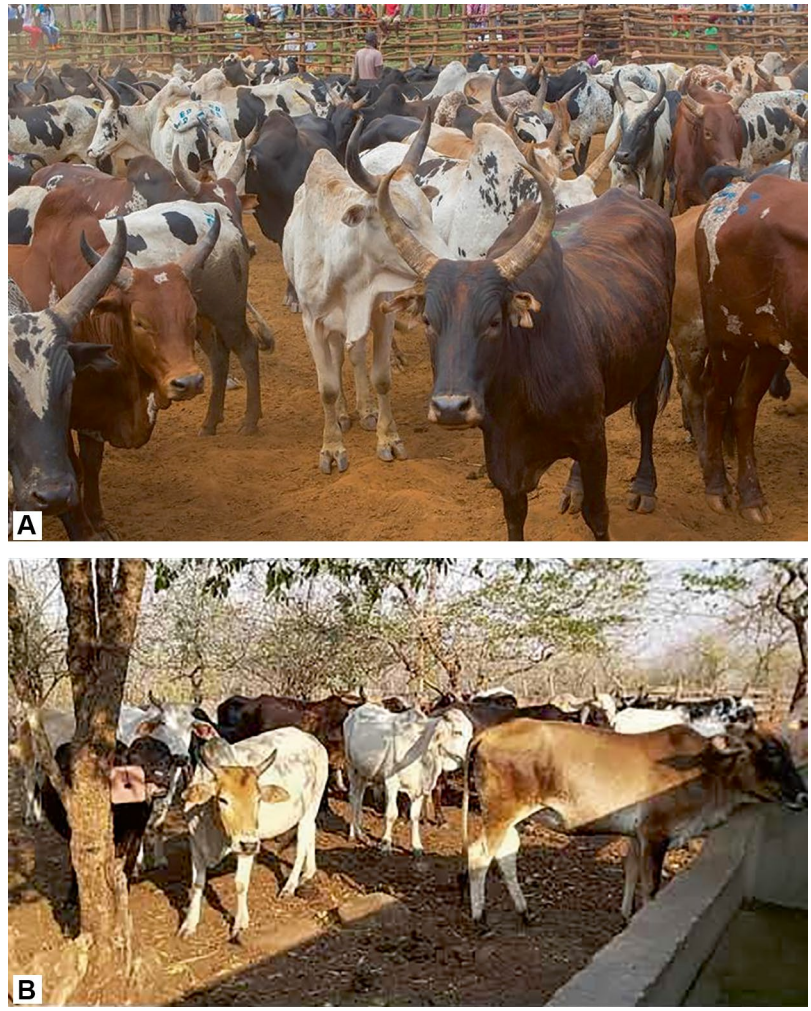

Fig. 4.7 (**a**) A herd of Madagascar Zebu. (Courtesy: Dr. Maria da Gloria Taela). (**b**) A herd of Malawi Zebu. (Courtesy: Dr. Patricia Mayuni)

Grouped under this category are the Azawak (found in Mali, Niger, and Nigeria), Djelli (Niger), Gudali (Cameroon and Nigeria), Maure (Mali, Mauritania, and Senegal), Tuareg (Mali), and Shuwa (Cameroon, Chad, and Nigeria). According to Gates (1952), these breeds have a common ancestry. They are known for their physical endurance that gives them the ability to survive in arid and semi-arid conditions. For example, the Gudali cattle are heavy and stocky animals that exhibit effective adaptability characteristics in both the humid and wet/dry and the arid conditions of the West and Central African sub-region. They are preferred for their meat production and draught power, while the White Fulani are preferred for both their milk and meat potential and trekking ability. The Shuwa cattle have similar endurance characteristics as well as high bodyweight at maturity (Rege and Tawah 1999) and are mainly reared for their dairy potential.

The Gudali Cattle

Classification, distribution, and population statistics: The Gudali cattle represents a large group of Shorthorn Zebus in West and Central Africa and comprises the Adamawa, Ngaoundere, and Sokoto subgroups, which are found principally in Cameroon, Nigeria, and the Central African Republic, with a small population in Ghana (Rege and Tawah 1999; Tawah and Rege 1996b). They are traditionally reared by Fulani and Hausa

Table 4.2 West and Central African Zebu Cattle

Breed name		Synonym
West and Central African Shorthorn Zebu		
1.1 Gudali	Adamawa Gudali	Banyo, Boyo
	Sokoto Gudali	Bokoloji, Godali, Sokoto
	Ngaoundere Gudali	Adamawa Fulani, Cameroon Fulani, Ngaundere
	Yola Gudali	Tattabareji, Tattabereji
1.2 Wadara or Shuwa cattle		Arab Shuwa, Arab Choa, Wadera
1.3 Azawak cattle		Adar (Nigeria), Shanun Adar (in Hausa), Azawa, Azawal, Azawaje (in Fulani), Arab (in Niger), Azaouak, Azouak, Darmeghou, Tagana, Tagama (Niger), Tuareg (in Burkina Faso), Touareg
1.4 Maure cattle		Arab, Mauritanian, Moor, Moorish
West and Central African Longhorn Zebu		
2.1 Gobra cattle		Senegalese Fulani, Senegal Zebu, Toronke
2.2 White Fulani		Bunaji, Yakanaji, Akou, Aku, White Bororo, Fellata, White Kano
2.3 Red Fulani cattle		Abori, Bodadi, Brahaza, Djafoun (Cameroon), M'Bororo, Mbororo, Red Bororo, Fellata (Chad and Ethiopia), Fogha, Gabassae, Gadehe, Hanagamba, Kreda (Chad), Ogha, Rahaji, Rahaza, Rahau, Red Longhorn, Wodabe, Wodaabe
2.4 Sudanese Fulani cattle		Peul Fulani, Bogoro Fulani, Fulani Nam, White Umboroa, Misse, Sego, Baouro, Bourgou, Toronke, Sambourou, Seno, Kaarta, Fellata, Bororo
2.5 Djelli cattle		Nigerian Fulani, Diali, Djali, Djeli, Jali, Jeli, Jalli, Peuhl, Tuareg, Tuoaureg

pastoralists. *Gudali* is a Hausa word for *'short-horned and short-legged animals'*. It is generally used to embrace a large group of Shorthorn Zebus, which are also referred to as *Fulbe* or *Peuhl* Zebu in West and Central Africa. Different names are used to designate these cattle populations (Table 4.2). These names are either based on their place of origin (e.g. Adamawa Gudali, Banyo Gudali, Ngaoundere Gudali, Sokoto Gudali, and Yola Gudali) or the owning tribe (e.g. Fulani Gudali, Fulbe Gudali, Peul, and Poulfoulo). In some cases, however, their dominant coat colour markings are used to designate them. For example, *Tattabareji*, a Fulani word for speckled coat colour, is used to refer to the Yola Gudali.

The ***Adamawa Gudali*** is primarily found in the Adamawa mountain ranges stretching from Nigeria to Cameroon. There are two sub-types: the **Banyo** or Boyo type found in the Banyo and Bamenda highland regions of Cameroon and the Mambilla highland regions of Nigeria (Taraba State) often have a white face and red eye patches or a red and white combination and, often, patches on their heads (Fig. 4.8a, b), and the **Yola** type are red, black, and white, often in patches. The Banyo type has rather large horns because of either Bunaji or Rahaji introgression (which one specifically is uncertain), while the Yola Gudali is considered to have a Muturu admixture (Gates 1952), and it has progressively been diluted since the 1950s, such that the Yola type is no longer recognized as a distinct variety by local herders (Blench 1999). Both the Kanuri and Fulani pastoralists in Nigeria own the Adamawa Gudali cattle. It is rare for these pastoralists to have herds of only Adamawa Gudali; they are often mixed with the Bunaji, Rahaji, and Wadara cattle (Blench 1999).

The ***Sokoto Gudali*** is commonly found in Nigeria, although small populations are also found in Burkina Faso, Ghana, Mali, Niger, and Northern Benin (Tawah and Rege 1996b). The population in Ghana is about 10,000, and most of them have been used for crossbreeding with the Ghana Shorthorn. In Nigeria, the breed used to be mainly found in the north-western region but is now widely distributed across the country. About 90% of the Sokoto Gudali are owned and managed by Fulani and Hausa pastoralists and transhumant herders, who graze their cattle on communally owned grazing lands and browse especially in the dry season (Tawah and Rege 1996b).

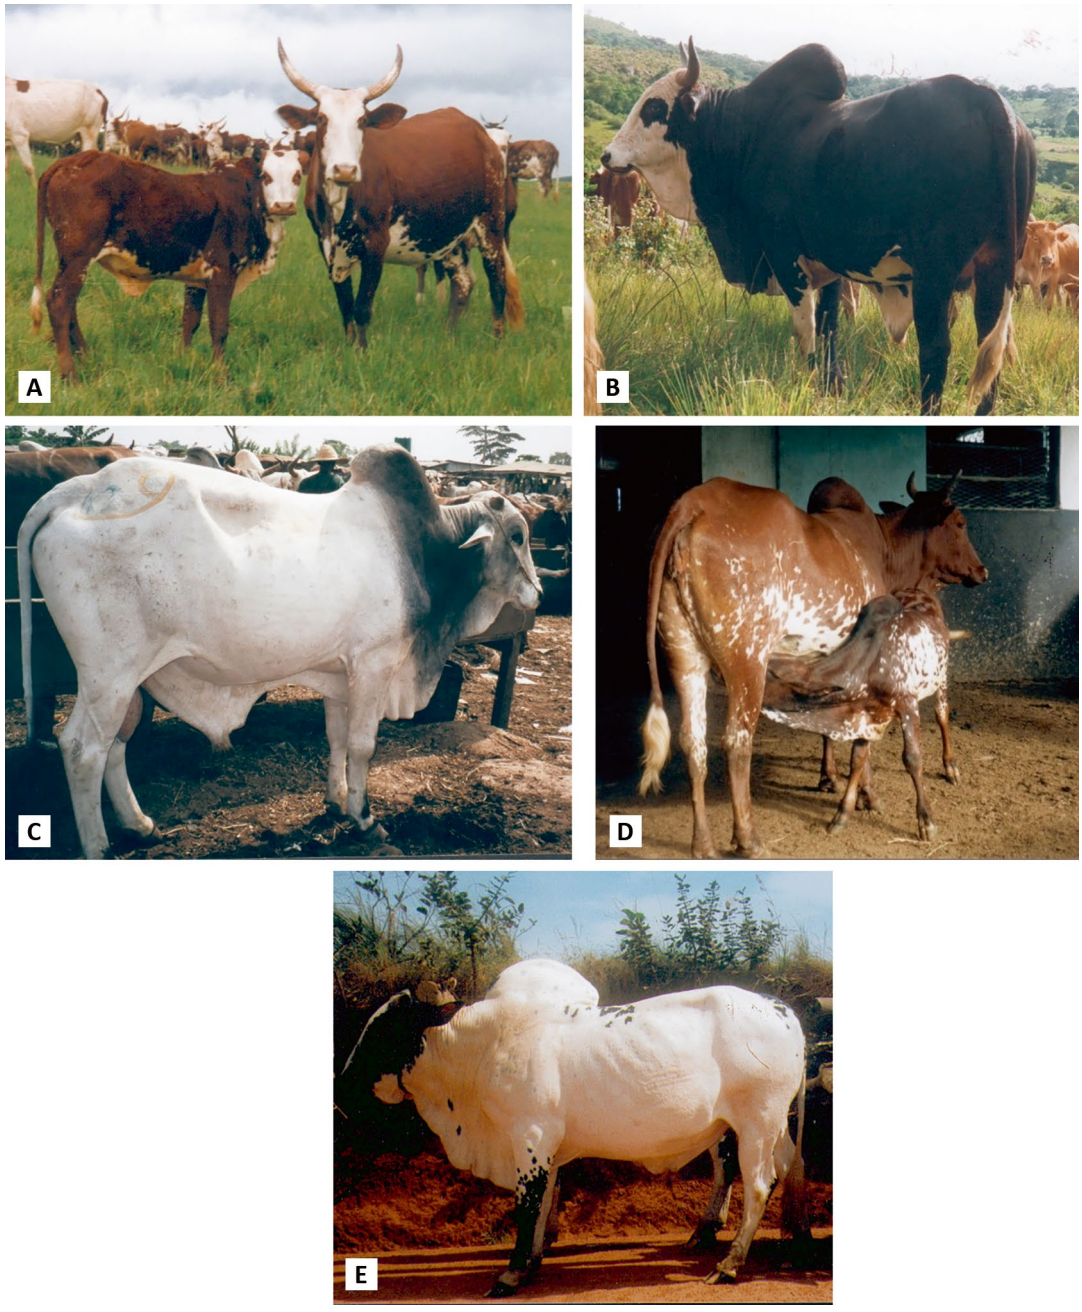

Fig. 4.8 (**a**) Typical Banyo Gudali cow and calf and (**b**) mature bull at Sabga, Cameroon, portraying the typical physical characteristics of the breed. (Courtesy: Dr. Eveline M. Ibeagha-Awemu). (**c**) Sokoto Gudali bull (Nigeria). (Courtesy: Dr. Eveline M. Ibeagha-Awemu). (**d**) Typical Ngaoundere Gudali cow and calf and (**e**) bull (Cameroon). (Courtesy: Dr. Eveline M. Ibeagha-Awemu)

The ***Ngaoundere Gudali*** is mainly found in the Adamawa region of Cameroon, with some populations also in the Central African Republic.

Accurate estimates of the population sizes of the various Gudali breeds/strains are not available because of their frequent movements inside

and outside their ecological zones and the overlap in their ecotypes. However, the population of the Sokoto Gudali has previously been estimated at about 4.35 million in Nigeria, the Banyo Gudali at about 140,000 in Cameroon, the Ngaoundere Gudali at about one million in Cameroon and 400,000 in the Central African Republic, and the Adamawa Gudali at about three million in Cameroon and Nigeria (Rege 1999; Tawah and Rege 1996b).

Physical characteristics: Tawah and Rege (1996b) have described the physical characteristics of the different types of Gudali cattle. They are similar in conformation, size, and origin to the Large East African Shorthorn Zebu and closely resemble the Boran and Kenana cattle (Sect. 4.1.1).

The ***Adamawa Gudali*** resemble the White Fulani (Bunaji) in conformation and are medium- to large-sized, with medium-length, thick, and crescent-shaped horns. Their large and pendulous hump is the main characteristic that differentiates them from the White Fulani. The coat colour varies from pied, white, black, and brownish yellow to red and white, black and white, and grey with brown spots. They have a well-developed dewlap and a short-to-long and narrow head and muzzle.

The ***Sokoto Gudali*** have long and broad ears, well-developed humps, and a pronounced sheath in the male (Fig. 4.8c). The hump is thoracic in position. Horns are short and almost absent in males but tend to be longer in females. There are large variations in coat colour in the breed. The most common coat colour is black and white with a light underside. However, uniform cream, light grey, or dun is also frequent. Colour variations exist and include grey and white or light dun with dark shading over the head, neck, and shoulders. The tail switch is black. The head is long and wide between the eyes and across the forehead, with a straight or slightly convex facial profile. Their dewlaps and skin folds are highly developed. The hair is short, and the skin is thick and pigmented. Ears are long, large, and convex, sometimes pendulous, although not to the same degree as in some of the Indo-Pakistan Zebus such as the Sahiwal.

The **Ngaoundere Gudali** are mostly reddish brown with white markings on the underside and sides; brindle and roan animals are also frequent, as well as spotted reddish individuals in white and brown coats (Fig. 4.8d, e). The dewlap, sheath, and umbilical folds are poorly to moderately developed. The horns are short-to-medium in length and crescent-shaped. The hump of the Ngaoundere Gudali is very large and pendulous, generally hanging over on one side and having the appearance of being broken.

Height at withers for males is 133–136 cm for Ngaoundere Gudali, 122 cm for Yola Gudali, and 130–137 cm for Sokoto Gudali, while for females, it is 123 cm for Ngaoundere Gudali and 117–131 cm for Sokoto Gudali. Heart girth for males is 190–194 cm for Ngaoundere Gudali and 190 cm for Sokoto Gudali, while for females, it is about 170 cm for Ngaoundere Gudali and 144–166 cm for Sokoto Gudali. Body length for males is 158–179 cm for Ngaoundere Gudali, 88 cm for Yola Gudali, and about 154 cm for Sokoto Gudali, while for females, it is 145 cm for Ngaoundere Gudali, 76 cm for Yola Gudali, and 124–145 cm for Sokoto Gudali. Despite the differences in conformation and other physical features, what the Gudali group has in common includes the long, well-balanced, and relatively compact, deep, and wide body and well-sprung ribs. They have deeper bodies than the White Fulani and present a close-to-the-ground appearance.

Production systems, husbandry practices, and production characteristics: Gudali cattle are raised under different traditional husbandry practices in different habitats and production systems. These include communal grazing and short- and long-distance transhumance pastoral systems. Long-distance transhumance occurs in the dry season when herders move southwards in search of pasture and water. When the rains return, there is a reverse movement while ensuring that the tsetse-infested and flooded areas are avoided. During transhumance, lactating cows are left with the offspring in the homestead and cared for semi-intensively (grass and occasional concentrates offered in addition to field grazing). Other than the castration of unwanted bulls, which is a

common practice, breeding is generally uncontrolled. The Gudali are also raised in ranches, on research stations, and on government-owned farms in the sub-region. The ranches may be state-owned or privately owned.

As alluded to above, Gudali cattle are heavy and stocky animals. They are well-known for their meat and milk qualities (Yakubu et al. 2010) and for their draught power. They are used for ploughing and carting because of their sturdiness and docility despite their slow and sluggish nature. Bullocks are usually out to work at 3 or 4 years of age. Gudali cattle have been shown to respond well to intensive feeding (Lhoste and Dumas 1972; Olayiwole et al. 1981) and are, thus, believed to be the most promising beef animals in the sub-region (Leclercq 1976; Olutogun 1976; Pagot 1985).

Tawah and Rege (1996b) and Rege (1999) have reported large variations in weight at maturity between and within the Gudali sub-types as follows: male mature weights are 400–563 kg for Ngaoundere Gudali, 400–408 kg for Banyo Gudali, 495–660 kg for Sokoto Gudali, and 350–352 kg for Adamawa Gudali. Female mature weights are 330–408 kg for Ngaoundere Gudali, 360–363 kg for Banyo Gudali, 240–355 kg for Sokoto Gudali, and 335–336 kg for Yola Gudali. Mature weights of oxen (castrated bulls) are 350–499 for Ngaoundere Gudali, 453 kg for Banyo Gudali, and 509–662 kg for Sokoto Gudali. Management practices are important contributors to the differences in mature weights. The Adamawa Gudali is considered a multipurpose breed, used as a draught animal and for beef and milk production. It fattens easily on grazing and is very docile. They respond easily to the use as draught animals and, for this reason, are favoured by locals for ploughing. However, when they become too large to pull a plough effectively, they are fattened and sold as meat animals (Babayemi et al. 2014).

Gudali cattle are also good milkers; the udders in the female are well-developed with good teats, and hence, they are regarded as an indigenous dairy breed. The lactation length for the milking cows is about 228 days, with a daily milk yield averaging about 7.5 kg. Sokoto Gudali cows produce an average of 1500 kg of milk per lactation. They produce more milk than White Fulani cows under similar research station conditions (Alphonsus et al. 2012). The age at first calving ranges from 38.6 to 49.5 months, and the calving interval ranges from 360 to 537 days (Tawah and Rege 1996b). The long interval between calvings is because of the ovarian inactivity in the postpartum period, coupled with high rates of abortions and stillbirths (ranging from 4.7% to 5.9%) in the breed.

Adaptive and special genetic characteristics*:* Gudali cattle exhibit adaptability to both humid, wet, dry, and arid conditions and are also known for their hardiness in the arid environments in the north. Sokoto Gudali are reputed for browsing, and herds are usually seen lopping trees towards the end of the dry season (RIM 1992). Buvanendran et al. (1992) reported rectal temperatures of 38–39 °C and 38.5–39.1 °C, respiration rates of 19.9–38.3, and 24.9–42.6 flank movements per minute, respectively, for Sokoto Gudali in the cool and hot seasons in Nigeria. Using these values, corresponding coefficients of adaptability to heat stress for these animals were estimated at 1.77–2.69 and 2.09–2.87. A higher value of this coefficient indicates poor adaptability to heat stress. Also recorded was a sweating rate of 54.7–93.3 and 170.8–224.1 g per m^2 per hour. These results show that Sokoto Gudali cattle are less adapted to the conditions of the Guinea savannah than White Fulani cattle (Buvanendran et al. 1992; Ngere 1985).

Microsatellite, milk genes, and milk and blood protein polymorphism studies of the Zebu and taurine cattle of Western and Eastern Africa (Braend and Khanna 1968; Braend 1971; Queval et al. 1971; Ibeagha-Awemu et al. 2004) have revealed that the Gudali and other Zebu breeds in the region may share the same evolutionary history with the Indo-Pakistan and Eastern African Zebus. Similarly, there is evidence that the Zebu cattle are distinct from the Shorthorn and Longhorn Taurine cattle of West and Central Africa (Ibeagha-Awemu et al. 2004). The Y chromosome is acrocentric in these Zebus and submetacentric in the taurine Baoulé and N'Dama cattle of West Africa and the European taurine

breeds (Popescu 1980). Moreover, Braend and Khanna (1968) observed that blood factor Z' is common in the Gudali and Fulani Zebus but absent in the Muturu and N'Dama cattle. Thus, there is a clear genetic distinction between the Taurine and Zebu cattle. These polymorphic systems can also be used as genetic markers for investigating the genetic relationships between these populations and their genetic purity.

The Wadara or Shuwa Cattle

Distribution and population statistics: The Wadara or Shuwa cattle are typical short-horned Zebu and are also known by various synonyms (Table 4.2). They are found throughout Chad (except the south-west), in north-eastern Nigeria, and in the extreme north region of Cameroon. The Wadara cattle in Nigeria are considered the indigenous cattle of Borno State and are often referred to as '*our cattle'* by the Koyam, Shuwa, and related pastoralists. Wadara cattle are considered to have some humpless Shorthorn gene introgression, although they are phenotypically predominantly Zebu. They represent 6.6% of the Nigerian herd (RIM 1992). They are also frequently referred to as 'Shuwa' in the literature, after the Shuwa Arabs who also keep them. A related breed, known as *Ambala*, is found throughout the Lake Chad region. The Ambala are said to often migrate into Nigeria from Chad. Their population is estimated at 4.55 million (Rege 1999).

Physical characteristics: The Wadara are small but well-muscled, medium-sized, lightly to deeply built animals with rounded ribs. Their coat colour is usually dark red or plain red, black, pied or brown, and sometimes, black and patchy. They are short-horned and have a small erect hump. Their height at withers is 135–140 cm in males and 125–128 cm in females (Rege 1999). The *Ambala* have a white coat or are dappled. Figure 4.9 shows mature male and female Wadara (Shuwa) cattle portraying the typical physical characteristics of the breed.

Production characteristics and uses*:* The Wadara are good dairy animals, with milk yields of 450–1820 kg in a 240–370-day lactation period. Consequently, like the Kenana and Butana cattle of eastern Africa, they are mainly reared for their dairy potential (Belemsaga et al. 2005; Kubkomawa 2017). Mature weights are 350–475 kg for males and 250–300 kg for females (Rege 1999). These animals are also used for riding and as pack animals. The Ambala ecotype is a large-sized animal and has a much larger mature weight of about 800 kg.

Adaptive characteristics: The Wadara have similar endurance characteristics to the other members of the Shorthorn Bos indicus family of the West and Central African Zebu population (Rege and Tawah 1999).

The Azawak Cattle

Distribution and population statistics: Azawak cattle are indigenous to the Azaouak region situated at the borders between Niger and Mali. *Azaouak* means sandy land without any vegetation in Tamajeq. Azawak cattle are raised by nomadic Tuareg and Arab inhabitants of the Azaouak valley, which is a vast, windy depression, stretching 3°–7° E longitude and 15°–20° N latitude and covering the arid eastern Mali and extending from the Niger River through southern Niger to parts of northern Nigeria. A small population of Azawak cattle is found in Nigeria throughout the year and constitutes about 0.7% of the national herd, while the majority are seasonally transhumant. They are generally found on the border to the North and West of Sokoto and North-West of Borgu. They are also dotted along the frontier from Sokoto to Katsina (Meghen et al. 1999). Azawak cattle are also referred to by different synonyms (Table 4.2). They are the most important cattle population in Niger, representing about 33% of the national cattle herd, and are found throughout the country. They are also found in Benin, Burkina Faso, the Central African Republic, and Chad. Their overall population is estimated at about 506,000 (Rege 1999). They have been used in crossbreeding with the Sudanese Fulani Zebu in Burkina Faso.

Physical characteristics: The Azawak are lightly built, average in size, stocky-shaped, and compact and are, therefore, suitable for beef production. Their coat colour is usually a mixture of

Fig. 4.9 Wadara or Shuwa cattle: a bull and a herd

red and white, black and white, fawn with white patches, or fawn red. On traditional farms, white, grey, and black are common, while on experiment stations, mahogany is common. The Azawak cattle in the Niger Republic are commonly red, while those found in Nigeria are usually light fawn, though they can also be white, brown, pied, and black. The dewlap is well-developed. The hump is large and narrow (12–16 cm thick). They have medium-length horns, which are short and thick at the base in males and lyre-shaped in females. Ears are 21 cm long in cows. The skin is flaccid with average thickness. The height at withers for males is 120–135 cm, and for females, it is 110–130 cm (Rege 1999). Figure 4.10 shows mature male and female Azawak cattle portraying the typical physical characteristics of the breed.

Production characteristics and uses: The Azawak are suitable for beef and draught. The average mature bodyweight of males is 350–500 kg and 250–410 kg for females in traditional systems (Rege 1999). However, males can attain mature weights of up to 600 kg on-station. They are early-maturing and aesthetic animals. Birthweight averages 23–24 kg for males and 21–22 kg for females. Carcass yield ranges from 48 to 52%. Their daily milk yield averages 1.5 kg over an average lactation length of 290 days (Traore et al. 2015), but they are able to produce between 5 and 15 litres of milk daily under favourable conditions. The age at first calving ranges from 35 to 40 months, with a calving rate of 70–75% and a calving interval of 11–13 months. Their average mature weight of 345 kg and high carcass yield account for the breed's suitability for meat production. Azawak cattle have been under selection at the Toukounous Sahelian Experiment Station in the Republic of Niger since the 1950s.

Adaptive characteristics: The Azawak are hardy and well-adapted to drought conditions and the general harsh climatic conditions of Niger and the surrounding environments. They have similar tolerance and endurance qualities as the Maure cattle. Their physical endurance, coupled with their ability to walk long distances, makes them highly suitable for pastoral farming (Traore et al. 2015).

The Maure Cattle

Distribution and population statistics: Maure cattle, also known as Moorish cattle and other synonyms (Table 4.2), are found in the Sahel region of Mauritania and the adjoining regions of Mali. They are owned by nomadic Arabs and Berbers. The humps are more prominent in the eastern part of their distribution range, suggesting possible Fulani influence. These animals are also in Côte d'Ivoire, Mali, and Senegal. Their population is estimated at about 673,000 (Rege 1999).

Physical characteristics: The coat colour of the Maure is fawn, red, or black in plain or patchy pattern. However, the most common coat colour is black or black and white, although dark red

Fig. 4.10 Azawak cattle in Niger. (Courtesy: Larry W. Harms, Virginia)

coats are common in the east. The Maure cattle are loosely built and tend to be leggier than the Azawak cattle. The height at withers ranges from 125 to 140 cm in males and from 110 to 130 cm in females (Rege 1999). Figure 4.11 shows a mature Maure cow portraying the typical physical characteristics of the breed.

Production characteristics and uses: Maure cattle have a large and stocky body size, making them suitable for beef production. Their mature bodyweight is about 250–700 kg for males and 250–350 kg for females (Rege 1999). Cows are valued for their milk yield, which averages between 471 and 650 kg over a lactation period of between 210 and 270 days. Milk yield per day is about 8.0 kg at peak lactation. They are also used as pack and riding animals.

Adaptive characteristics: Maure cattle have a strong muscular body, which makes them suitable for draught power (Penda et al. 2014). They also show a high tolerance for high temperatures and low-humidity conditions and, hence, their preference by farmers in the arid parts of Mali. Moreover, they are adaptable to varying temperatures and are, thus, able to survive in the high humidity conditions of Côte d'Ivoire and Senegal (Santoze and Gicheha 2019).

4.1.3.2 West and Central African Longhorn Zebu

The longhorn *Bos indicus*–type of the West and Central African Zebu cattle, also known as the Fulani type, includes the ***Gobra, White Fulani, Red Fulani, and Djelli*** cattle. Their origins are not known. Tawah and Rege (1996a) have summarized existing theories about their genetic constitution, including evidence suggesting that they are an admixture of *Bos taurus* and *Bos indicus* ancestry. This theory is supported by a report of more than 7% African taurine and more than 10% European taurine genetic influence in the White Fulani and Red Fulani populations of Cameroon and Nigeria, based on the data on 225 alleles at 28 loci (Ibeagha-Awemu et al. 2004). Indeed,

Fig. 4.11 Maure cattle. (Courtesy: Dr. Larry W. Harms, Virginia)

while the Fulani people are thought to be conservative pastoralists, their livestock management practices suggest that they do cross and change cattle breeds to adapt to new ecological or socio-political conditions (Boutrais 2007).

The Fulani cattle are a unique group in West and Central Africa, which differ from the typical Shorthorn Zebu of Central, Eastern, and West Africa by the presence of long horns and from the cervico-thoracic-humped Sanga cattle by the presence of a thoracic, or sometimes, intermediate hump. The Fulani family has been classified into two subgroups: the lyre-horned subgroup consisting of the Gobra (Senegalese Fulani), the Sudanese Fulani, and the White Fulani, also known as Bunaji in Nigeria and Akou in Cameroon, and the long lyre-horned subgroup represented principally by the Red Fulani, also known as Rahaji in Nigeria (Payne 1970; Mason 1988). Rege and Tawah (1999) have described the Djelli (or Diali) as a strain of the Fulani family found on the floodplains and adjacent valleys of the Niger River in the Niger Republic and south-west Nigeria. Blench (1999) described the Djelli as exotic to Nigeria. Recent reports show that the Fulani cattle are characterized by a high degree of genetic diversity (Ibeagha-Awemu et al. 2004; Ibeagha-Awemu and Erhardt 2006; Nourezzine et al. 2019). Moreover, there is a high genetic connectedness between the Red and White Fulani (Ibeagha-Awemu and Erhardt 2006) as well as the Kuri cattle (Epstein 1971). Individual members of the Fulani family are described in the following paragraphs.

The Gobra Cattle

Distribution and population statistics: The Gobra is the dominant breed in the Sahelian belt of Mali and Senegal and in the adjoining regions of Mauritania. They are referred to as the Toronke Cattle in Mali. Their population is estimated at about 1.3 million (Rege 1999). The Gobra cattle are also known by different names such as the Senegalese Fulani, Senegal Zebu, or Toronke (Table 4.2).

Physical characteristics: Gobra cattle have either lyre-shaped or crescent-shaped horns, which are sometimes loose and can reach 70–80 cm in length. Their dewlap is well-developed. Their hump is prominent, especially in the adult males. They have thick and loose skin. Most of the cattle are grey with dark patches, but animals with white backs and black speckles are not uncommon. The Gobra and White Fulani cattle are predominantly white in coat colour and are much larger than the Sudanese Fulani, whose coat colour is quite variable but usually spotted light grey. The Gobra cattle have an average height at withers of 130–144 cm for males and 124–140 cm for females. They have a heart girth

Fig. 4.12 Gobra cattle. (Courtesy: Dr. Larry W. Harms Virginia)

of 171 cm and a body length of between 70 and 127 cm. Figure 4.12 shows mature male and female Gobra Zebu cattle portraying the typical physical characteristics of the breed.

Production characteristics and uses*:* Gobra cattle possess an average weight at maturity of between 300 and 578 kg for males and between 250 and 450 kg for females (Rege 1999). Sexual dimorphism is marked between males and females, with significant differences. The age at first calving is about 44.8 months, and the interval between calvings is about 15.5 months. They are mainly kept for meat production because of their high mature bodyweight, but they can also produce about 675 kg of milk over a 330-day lactation period (Missohou et al. 1997). The bulls and oxen are used for riding and as pack animals.

Adaptive characteristics: Because of their physical endurance in the arid and semi-arid conditions, Gobra cattle are preferred in pastoral production systems.

The White Fulani Cattle

Fulani is the Hausa word for the pastoral peoples of Nigeria belonging to the 'Fulbe' migratory ethnic group. Pastoralism, as a livelihood, is coming under increased pressure across Africa, including among the Fulbe owners of Fulani cattle, due to changing socio-economic and environmental conditions. In the past (especially, the 1950s and earlier), there was a symbiotic relationship between pastoralists (practising transhumance) and the more sedentary crop farmers. During the dry season, pastoralists migrated to the pasture-rich areas with minimal cropping in the southern parts of the Guinea savannah zone. During the rainy seasons, pastoralists would migrate away from the tsetse-infested forest areas towards the northern Sudan savannah zone, supplying dairy products to the local farming community and avoiding trypanosomosis. The farming community supplied pastoralists with grain, and after the harvest, cattle were permitted to graze on crop residues in the fields, leaving behind valuable manure and the fields ready for the next cropping season.

Today, population pressure has resulted in deforestation and increased settlement in the Guinea savannah and rainforest regions. At the same time, the control of tsetse and trypanosomosis has enabled cattle and crop farmers to inhabit these zones all year round. This has increased the competition for resources, including land, with grazing areas and transhumance routes coming under pressure and crop land being increasingly limited. With pastoralists having limited or no rights to land, there are intense conflicts when livestock damage crops. The situation is getting worse with climate change and its

impacts on the reliability of rains and, hence, the availability and access to water and pasture.

Distribution and population statistics: The White Fulani cattle are the most numerous and widespread of all the Nigerian cattle breeds, representing about 37.2% of the national cattle population (FDLPCS 1992; Alphonsus et al. 2012; Kubkomawa 2017), and are distributed in an area stretching from the South-western states, across the middle belt to Sokoto, Katsina, and Kano states. In Cameroon, where their distribution stretches from the Adamawa, Far North, to the North-west Regions of the country, they represent 33% of the national cattle herd and are only second to the Red Fulani (Tawah and Rege 1996a; Messine et al. 1995), and in Ghana, the White Fulani constitute about 80% of all Ghanaian Zebus (Aboagye 1995). They are also represented in small populations in the Benin Republic, Chad, Niger Republic, and Sudan. They are known by different names (Table 4.2) and are found in both tsetse and non-tsetse-infested agro-ecological zones of West and Central Africa. The population of the breed is estimated at about 9.67 million (Rege 1999).

Physical characteristics: The White Fulani are medium-to-large-sized animals with a well-balanced body of good depth and width. Height at withers is 130–152 cm for adult males and 118–138 cm for adult females. Heart girth is 193 cm for males and 145–161 cm for females, while body length is 152 cm for males and 117–137 cm for females. They are of good length and have a marked slope from the hook to the pin bones, which tend to be narrow in some animals. The barrel is well-sprung and of good capacity, and the top line is strong and slopes gently from the hump to a somewhat high sacrum. The hump is well-developed in the males than in the females and sometimes tends to hang over at the back in the former, like that of the Gudali. The hump is either thoracically or cervico-thoracically placed on the backline and is musculo-fatty. The tail is thin and long, with the tail switch almost touching the ground. The White Fulani have light and hard bones and a well-developed and large dewlap, especially in the bulls. The head is long and of good proportion and is straight or slightly dished (concave). The neck is strong and deep, providing an upright carriage for the head. Figure 4.13 shows mature male and female White Fulani cattle portraying the typical physical characteristics of the breed.

The White Fulani have lyre-shaped horns, which are slender, well-proportioned, and of medium-to-long length, measuring about 80–107 cm. The horns are round in cross section and are curved outwards and upwards immediately above the head. Most of the White Fulani animals have horns with an outward twist at the tips, giving them the characteristic lyre shape. The ears are of medium size, erect, and set horizontally, with the inner parts having black points showing to the front. The udders are well-developed and of good shape and are strongly attached, and the teats are well-positioned and are of medium-to-large size.

White Fulani cattle have a predominantly white coat colour on a black skin with black ears, eyes, muzzle, hooves, horn tips, and tail tip. There are a few cases with black coat colour mixed with dark patches or red and white coat colours. Sometimes, red marks can be found on the ears, feet, and sides. Black flecking on the sides and limbs is quite common, while red markings are frequent. In some cases, variations in coat colour include combinations of black and white on a black skin or red and white on a white skin (Ogunsiji 1974). The skin is loose and pigmented with soft hair.

Production characteristics and uses*:* The White Fulani cattle are predominantly found in the tropical climate characterized by two well-defined seasons—the wet and dry seasons—and two prevailing wind systems—the south-west rain-bearing wind from the Gulf of Guinea and the dry north-easterly dust-laden wind (the harmattan). The vegetation varies from closed forest in the derived savannah to light forest and open woodlands in the Guinea savannah. Most trees in the Guinea savannah are fire-tolerant, and the major grass species have been described by (Tawah and Rege 1996a), with *Hyparrhenia* spp. being the most common. Luxuriant growth of many tall grasses, such as the Gamba grass (*Andropogon tectorum* and *A. gayanus*) and

Fig. 4.13 White Fulani bull (**a**) and cow and calf (**b**). (Courtesy: Dr. E. M. Ibeagha-Awemu)

Guinea grass (*Panicum maximum*), is characteristic of the derived and Guinea savannah zones.

The White Fulani are well-known for their dual-purpose characteristics and are mainly reared for their beef and dairy production (Rege and Tawah 1999). Their traditional owners rear them primarily for milk. Their dairy potential is much better than that of most Zebu cattle in the region but comparable to that of the Kenana cattle in Sudan (Osman 1984). White Fulani are also good beef animals and fatten quite well in feedlots and on natural pastures. Indeed, much of the beef consumed throughout Nigeria is from the White Fulani (Payne and Wilson 1999; Alphonsus et al. 2012). White Fulani bulls are good draught animals by virtue of their docility, tractability, conformation, and body size.

White Fulani cattle attain mature bodyweights of between 425 and 665 kg for males and between 250 and 380 kg for females in improved systems. Mature weight for females in traditional systems has been reported at 270–310 kg. Birthweights average between 18 and 20 kg in traditional systems and between 21 and 24 kg in improved systems. They reach sexual maturity late and have long intervals between calvings and short lactation lengths compared to the Sokoto Gudali (Kubkomawa 2017). The milk yield varies considerably from 720 to 2950 kg for a variable lactation length of between 196 and 427 days (Mrode 1988). The age at first calving ranges from 26 to 45 months, but in Fulani pastoralist herds, it can be as late as 60 months (Aganga et al. 1986).

Adaptive and special genetic characteristics*:* The White Fulani cattle are tolerant of intestinal helminths and are more resistant to dermatophilosis than the Muturu and N'Dama cattle (Nwufoh and Amakiri 1981). They are also known for their genetic predisposition for hardiness, heat tolerance, and adaptation to local conditions (Alphonsus et al. 2012). For example (Amakiri and Mordi 1975), reported that White Fulani cattle are more heat-tolerant than N'Dama and Sokoto Gudali in Nigeria, which is reflected in their low respiration rate and heat tolerance index. White Fulani cattle tend to pant and salivate less under heat stress (Buvanendran et al. 1992) and sweat much more profusely than Gudali, N'Dama, and Muturu cattle when exposed to similar high ambient temperatures (Amakiri and Onwuka 1980). Igono and Aliu (1982) described the White Fulani as the least stressed animal in the hot climates of Nigeria. They are superior to all the other breeds of Zebu in resisting diseases, with the ability to thrive under a variety of conditions (Blench 1993; Meghen et al. 1999). Their leggy appearance, which is from the shallowness of their body and lack of width, has been associated with their ability to trek long distances (Oyenuga 1967; Capitaine 1972). This attribute has been described as an adaptation to their nomadic lifestyle.

The Red Fulani Cattle

Distribution and population statistics: The Red Fulani cattle, also known by other names (Table 4.2), including *Rahaji* in Nigeria, are predominantly found in the arid and semi-arid regions of West and Central Africa. They are distinguished by their chestnut-to-deep mahogany coat colour and are the most striking of the Fulani family. They are found in northern Cameroon, southern Niger, and central and northern Nigeria. They are specific to the Bororo Fulani people of Cameroon, Niger, and Nigeria.

The Red Fulani is the second most numerous of the cattle populations in Nigeria, representing about 22% of the national herd, and the most numerous of the cattle populations in Cameroon, representing about 37% of the national herd (FDLPCS 1992; Messine et al. 1995). They are mainly located in the Far Northern States of Nigeria, although they are significantly absent in Borno State, where the Wadara cattle are predominant, and in the Adamawa, Far North, North, and North-west Regions of Cameroon. The Fulani pastoralists consider the Red Fulani as an extremely prestigious breed, and they are well-liked because of their beautiful appearance, high intelligence, and obedience to commands. Rege (1999) reported an estimated population of 4.92 million.

Physical characteristics: The Red Fulani cattle is one of the largest breeds in size (second only to the Kuri) in the region. They are distinguished by their deep burgundy-coloured coat and pendulous ears and horns that are gigantic—long (up to 63 cm) and thick. The hump is thoracically or cervico-thoracically located, well-developed, muscular in structure, and generally pyramidal in shape. Their dewlap, umbilical folds, and sheath are highly developed. Figure 4.14 shows Red Fulani cattle herds portraying the typical physical characteristics of the breed.

Production characteristics: The mature weight of the Red Fulani is between 400 and 450 kg for males and between 255 and 410 kg for females (Rege 1999). Their age at first calving ranges from 48 to 53 months, with the calving interval averaging between 537 and 585 days. The average milk yield per lactation has been estimated at 900 kg. In Cameroon, the daily milk production has been reported to range from one to two litres per cow, with a lactation length of 140–180 days (IRZ 1987).

Adaptive characteristics: The Red Fulani cattle are adapted to the arid and semi-arid regions and are susceptible to diseases in the humid areas (such as trypanosomosis) and poor nutrition. They are raised in conditions of low rainfall (3–5 months of rain, followed by a long dry season). They graze well on mature grasses, shrubs, and tree leaves and are well-noted for their herd instincts, walking gait, and ability to trek long distances (Mason 1996). They are also able to withstand heat, ticks, and insect bites.

The Sudanese Fulani Cattle

Distribution and population statistics: The Sudanese Fulani cattle, also known by other names (Table 4.2), are similar in origin to the Gobra of Senegal, with which they merge in transition zones. The Sudanese Fulani cattle are mainly owned by the nomadic Fulani people who occupy the belt between the Sahara and the coastal rainforest zones from the west of River Senegal to the east of Lake Chad, including parts of western Senegal, southern Mauritania, in and around the floodplains of Niger, Chad, northern Nigeria, and Cameroon (Rege and Tawah 1999). They are said to interbreed with the Azawak cattle in eastern Mali during seasonal migrations. The breed is found all over southern and south-western Mali, along the floodplains of the Niger River from Segon to Timbuktu. They are also found in Senegal. In both Senegal and Mali, they are known as the Toronke cattle. In Burkina Faso and Côte d'Ivoire, interbreeding with the humpless cattle is common. Sudanese Fulani have an estimated population of about 5.62 million (Rege 1999).

Physical characteristics: The horns of Sudanese Fulani cattle are either lyre-shaped or crescent-shaped in appearance. Most have grey coat colours with dark patches, but animals with white backs and black speckles are also common. The height at withers ranges from 120 to 138 cm in males, and from 115 to 126 cm in females

Fig. 4.14 Red Fulani herd (**a**) and bull (**b**). (Courtesy: Dr. E. M. Ibeagha-Awemu)

(Rege 1999). The Sudanese Fulani cattle are usually spotted light grey, although quite variable in coat colour. Figure 4.15 shows mature Sudanese Fulani cattle portraying the typical physical characteristics of the breed.

Production systems, husbandry practices, and production characteristics: The major habitat of the Sudanese Fulani, the Niger delta, is in the semi-arid zone and has rainfall ranging from 200 to 600 mm per annum. The vegetation is strongly influenced by the annual flooding of River Niger. The floodplain pastures consist mostly of tall grass formations, which give way to rain-fed shrubland and browse trees in areas characterized by late and irregular floods. The vegetation varies according to the flood regime and consists of high-quality *bourgou* pastures (*Echinochloa stagnina*) and perennial Gramineae, such as *Vetiveria nigritiana*, *Andropogon gayanus,* and *Oryza longistaminata.*

The herds begin transhumance with the first rains in July, moving from the dry delta to the Sahelian uplands in the north-west, where they remain from August to October, grazing rain-fed pastures (Wagenaar et al. 1986). They return to the delta in November/December when the flood has subsided and follow its withdrawal to the north until the next rains. Due to the sharp climatic contrasts between the single rainy season of 2–4 months and the long dry season, there are large seasonal variations in the quantity and quality of the range resources available in the Sahel.

Birthweights of 17 and 21 kg have been reported in the Sudanese Fulani herds in traditional systems and on the ranch, respectively. The corresponding weaning weights were 55 and 79 kg. Mature weights are between 280 and 345 kg for males and between 248 and 300 kg for females (Rege 1999). Live bodyweight of cows of 1–2 years of age has been reported at 210 kg, and the bodyweight of mature animals over 6 years old reached up to 500 kg, with an average of 384.7 kg (Hamza et al. 2021).

Adaptive *characteristics:* The Sudanese Fulani cattle are able to trek long distances of up to 300 km in search of grazing and water and are adapted to the arid and semi-arid conditions.

The Djelli Cattle

Origin, distribution, and population statistics: The origins of the Djelli cattle, also known by different names (Table 4.2), are contentious. Some believe that they were derived from the Dwarf West African Shorthorn, primarily a cross between the Shorthorn Zebu and *Bos taurus*. It is postulated that the Djelli cattle have a stronger *Bos taurus* ancestry (genetic background) than any other West African Zebu cattle. They are found in the river basin of Niger, throughout north-eastern Burkina Faso, the south-west corner of Niger, the neighbouring areas of northern Benin, north-western Nigeria around Lake Chad, and Cameroon. However, they are predominantly found in Niger, mainly in pastoral systems (Rege and Tawah 1999).

Physical characteristics: Djelli cattle are of medium build with lyre-shaped horns. They have short, slender limbs. Their chest is full and deep. Neckline and shoulders are short, while dewlap and hump are very marked. The back dips slightly

Fig. 4.15 Sudanese Fulani cattle. (Courtesy: ILRI)

behind the hump and the waistline is nicely rounded. The skin is supple and slightly thin. The head is long and has medium lyre-shaped horns. The coat colour is black and white in a speckled or patchy pattern, although the dominant colour is white. Some animals have piebald coats (i.e. dirty white with black spots). The Djelli cattle population in Nigeria has been influenced by its neighbouring Sokoto Gudali cattle because of the seasonal migrations of Fulani pastoralists. Figure 4.16 shows mature male and female Djelli cattle portraying the typical physical characteristics of the breed.

Production characteristics: They are used primarily for meat and animal traction and have good fattening capacity. They have a mature bodyweight of 300 kg and a height at withers of between 115 and 130 cm. The carcass yield ranges from 48 to 50%. The cows produce about 2–3 litres of milk per day on average.

Adaptive characteristics: Like the other members of the Fulani family, the Djelli cattle are believed to be highly tolerant of diseases and exhibit cross-environmental adaptability. They are known to be able to survive in the arid and semi-arid conditions in Niger and its surroundings.

4.2 The Sanga Cattle

The original African cattle are divided into two major categories, namely humpless (*Bos taurus*) and humped (*Bos indicus*) (Chap. 3). The latter category is subdivided into Zebu proper and Zebu crossbred types. The Sanga is an intermediate type of cattle, which is a cross between *Bos taurus* and *Bos indicus*. *Sanga*, an Ethiopian word meaning 'bull' or 'ox', relates to the origin and centre of dispersal of this group of cattle breeds (DAGRIS 2022). One school of thought about the origin of the Sanga posits that the Sanga likely evolved in Ethiopia from the interbreeding between the original longhorn humpless cattle with cervico-thoracic-humped (Zebu). These cattle were then spread southwards by Hamitic (Bantu) tribes migrating from north-eastern Africa about 600 years ago (Rege and Tawah 1999) into western and southern Uganda and to Rwanda-Burundi and adjacent areas, including the present-day Democratic Republic of the Congo. This theory is buttressed by the fact that food production and the keeping of cattle seem to have begun in the highland and Rift Valley regions of East Africa in the first millennium and have derived from peoples who were probably southern Kushites from Ethiopia.

The Sanga are humped, but the hump is cervico-thoracic rather than thoracic. The Sanga is nowadays considered a separate group of cattle. There are 30 Sanga cattle breeds and strains on the African continent. They are discussed here by geographical regions—eastern, southern, western, and central Africa. Rege (1999) categorized the Sanga of eastern Africa into three groups: Nilotic Sanga of Sudan and Ethiopia, the Abyssinian Sanga of Ethiopia and Eritrea, and the Ankole group of Burundi, Democratic

Fig. 4.16 Djelli cattle. (Courtesy Dr. Larry W. Harms, Virginia)

Republic of Congo, Rwanda, Tanzania, and Uganda. The Sanga cattle in southern Africa are classified into six clusters, namely, the Shona of Zimbabwe, the Nguni group of Angola and Zambia, the Ovambo, the Setswana group, and the Afrikaner group of Southern Africa. Table 4.3 summarizes the classification of the present-day Sanga breeds/strains of eastern Africa and southern Africa. The following sections summarize the Sanga of eastern, southern, and West Africa.

4.2.1 The Sanga of Eastern Africa

The Abyssinian Group of Sanga Cattle

The ***Danakil*** and ***Raya Azebo*** cattle breeds are known members of this group.

Distribution and population statistics: The Danakil (also known as Adal, Afar, or Keriyu) cattle are kept by the Afar people of north-eastern Ethiopia in the steppe and semi-desert areas of the Afar region of Ethiopia, south-eastern part of Eritrea (along the southern Red Sea coast), and northern part of Djibouti. The Danakil depression—which the breed is named after—lies in the central part of the distribution area. The breed has also spread along the Awash River to parts of the Western Hararghe and Eastern Shewa zones. The related breed known as Raya Azebo is kept by the adjacent Raya and Keriyu tribes in Eastern Shoa, South Wollo, and Western Hararghe. The population of the Danakil has been estimated at 680,500 (DAD-IS 2005).

Physical characteristics: The Danakil cattle have a straight profile; long, thin legs; and long horns, which measure 1 metre or more in length and are lyre- or crescent-shaped. In some cases, the two horns loop to form a complete circle. The animals have a straight back but with a sloping rump. Their average height at withers is 125–145 cm in males and 120–125 cm in females. Danakil humps are small and cervico-thoracic, and the dewlaps are small. The navel flap and preputial sheath are also small. Hind legs are bowed with weak hocks and thin thighs. Their coat colour is usually ash grey, cream, or light chestnut. Figure 4.17 presents pictures of typical Danakil and Raya Azebo cattle.

Production characteristics: The Danakil cattle are kept for milk, meat, and work but mainly for milk production. Male animals weigh 250–380 kg, while females weigh 200–305 kg. Their meat is very fibrous. Their milk production averages 200–300 kg in a lactation period of 160–225 days.

Adaptive or special genetic characteristics*:* The Danakil are able to cope with extended periods of drought. They are browsers and are able to walk long distances in search of the few scattered patches of coarse grasses that may be available during these periods.

The Ankole Group

Distribution and population statistics: These cattle are found in eastern and central Africa and comprise the *Bahima, Bashi, Kigezi, Nsagalla,*

Table 4.3 The Sanga cattle breeds of eastern and southern Africa

		Estimated populationa	Mature weight (kg)		Withers height (cm)		Main users
Group and breed/strain	Location/ country		Male	Female	Male	Female	(in the order of importance)

Ruzizi, and *Watusi* (FAO 2010). Ankole cattle are generally classified in the wider group of the Sanga cattle. It is considered that Ankole cattle, with their characteristic long horns, further evolved from the original Sanga around the present-day Uganda, developing further into the local strains/sub-populations (Felius 1995). This position is also supported by Banyankole mythology that Ankole cattle were domesticated in their current location by the Bachwezi, a semi-mythical people (Infield 2003). The central and eastern African 'Ankole cattle region' is also generally referred to as the inter-lacustrine or Great Lakes region, as it is bordered by Lakes Victoria, Kyoga, Albert, George, Kivu, and Tanganyika. The Bahima and Nsagalla strains are considered by some to be the same and should not be separated (Bett et al. 2013). These strain names were derived from the tribal names of their traditional owners. The *Bahima* are kept by the Bahima race of the Banyankole tribe of Uganda, the *Kigezi* are kept by the Banyakigezi/Bakiga tribe, the *Bashi* are kept by the Bashi people in the Democratic Republic of Congo, and the *Watusi* are reared by the Tutsi people of Rwanda. A particular lineage of the Watusi called Inyambo is descended from the Tutsi kings who ruled the Rwanda-Urundi kingdom and is currently reared in Eastern and Northern Rwanda. The *Ruzizi* is found in the Ruzizi Valley between Lake Tanganyika and Lake Kivu. In Uganda, the Ankole is the prevalent type of cattle, found in the western, central, and south-western parts of the country (Nakimbugwe and Muchunguzi 2003). The multiplicity of strains notwithstanding, the Ankole are mainly owned by the Bahima pastoral communities (Kajura 2001) in the districts that form the Ankole region (Lamwaka 2006) and other districts of the cattle corridor.

Physical characteristics: Ankole cattle typically have a rusty dark red coat colour, but dun and black coat colours are not uncommon. The coat colour is usually solid, but they can also be spotted or speckled. Both males and females have large horns, which spread up to 2.4 metres long and are considered the largest horns of any cattle in the world. The body is of medium size, the neck is relatively short, and the legs are weak.

Production characteristics and uses*:* The Ankole is used for meat and milk production, draught power, and many cultural functions such as funerals, weddings, or religious sacrifices (Infield 2003; Kugonza et al. 2011). Cows have excellent maternal abilities. Ankole meat has low fat content compared to that of other breeds in the region and specialized beef breeds. The skin was traditionally used for making cultural regalia like drums, stools, sandals, and clothing. Indeed, the Ankole cattle hold a central role in the culture and lives of the Bahima (Bonte 1991; Schoenbrun 1993), and their economic contribution is critical to the livelihoods of these communities (Infield 2002). The height of mature animals ranges from 165 to 198 cm. Birthweights range from 4.7 to 6.8 kg. Mature males weigh 450–720 kg, and females weigh 405–540 kg. Milk yield is about

500 litres over a 240-day lactation period (DAGRIS 2022). At 7%, the butterfat content of Ankole milk is quite high. In areas of land scarcity (Burundi, Rwanda, and western Uganda), a clear trend from pure Ankole cattle towards crossbred animals can be observed, and recent studies (Wurzinger et al. 2006; Kugonza et al. 2011) show that these cattle are increasingly under threat from crossbreeding with taurine breeds.

Adaptive or special genetic characteristics*:* The Ankole are hardy and efficient grazers, with the ability to thrive on rough forage. An attribute commonly mentioned by Ankole keepers is their (general) disease resistance.

Ankole were first introduced to the United States in the 1960s from a small seed stock in European zoos. Today, fewer than 1000 purebred Ankole animals are registered in the United States. Figure 4.18 shows typical Ankole animals with their characteristic horns.

The Nilotic Group

This group is composed of the *Abigar, Aliab Dinka, Aweil Dinka, Nuer*, and *Shilluk* cattle breeds.

The Abigar

Distribution and population statistics: The home of Abigar cattle is the lowlands of south-west Ethiopia, around the border with Sudan, along the White Nile, in the area covering the Akobo area of Gambella. It is considered a sub-type of the Nuer cattle (Rege 1999) and is reared and maintained by the Nuer tribes of Gambella Regional State. Abigar is the dominant cattle type in the region and plays a major role in the socio-cultural and economic life of pastoral and agro-pastoral communities that depend on it. The breed has a population of 548,600 heads.

Physical characteristics: The Abigar cattle possess a wide array of coat colour patterns, with white/cream being the most dominant. Mean heart girth circumference is 142.5 cm in females and 148.9 cm in males, and the height at withers is 114 and 118.3 cm, respectively. Figure 4.19 shows an Abigar and a herd.

Production characteristics and uses*:* Abigar cattle are mainly reared for milk and meat and as a source of farm power. The daily milk offtake per cow is 1.3–3 litres (Minuye et al. 2018), the mean lactation length is 8–9 months, and the lifetime calf crop production is 7.4–10 calves (Mureja 2002). The breed is the major source of milk and milk products for the people in the Gambella Region. The average age at puberty has been reported to be 36.2 months, while the age at first calving and calving interval were 42.5 and 14.1 months, respectively, under extensive management (Minuye et al. 2018). Overall, the breed is a productive breed, considering its harsh environment—disease prevalence and frequent droughts—and the extensive management. Abigar animals are docile and easy to handle.

Adaptive or special genetic characteristics*:* Abigar is known for its tolerance to tsetse fly challenge, high heat load, and periodic flooding.

The ***Aliab Dinka*** breed is found in south-east Sudan and the ***Aweil Dinka***—the smaller-sized of the two—in the north-west territory of Sudan (Rege 1999). The Aliab Dinka cattle are owned by a tribe of the same name—a subdivision of the Dinka people of South Sudan. They traditionally lived in an area west of the upper White Nile River. The cattle have white, grey, or light fawn coat colours, large bodies, long horns, and small cervico-thoracic humps.

The ***Shilluk*** breed neighbours with the other strains and is more diffuse. These cattle are owned by the agro-pastoralist, Nilotic-speaking Shilluk people, who form part of the larger Luo ethnic group of South Sudan. They live on both banks of River Nile, around the city of Malakal, and between Lake No in the south and Kosti in the north, extending on the east bank of the Nile as far as Anakdier in the east. The area has flat-lying plains with moderate rainfall. Vegetation is made up of thick, tall grass and a few trees and shrubs.

4.2.2 The Sanga of Southern Africa

This group of Sanga cattle is further subdivided into six breed clusters or groups, namely, the

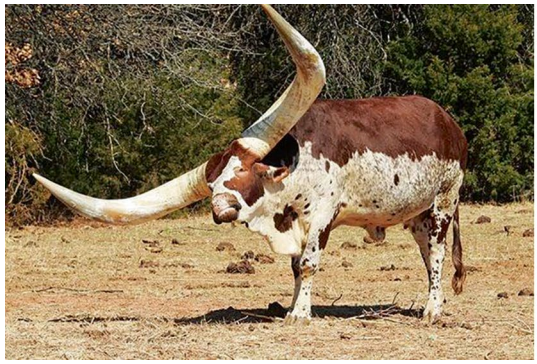

Fig. 4.18 Ankole bull and herd showing their characteristic lyre horns. (Courtesy: Dr. Donald Kugonza)

Shona subgroup, the *Nguni* cluster, the Zambia/Angola cluster, the *Ovambo* and south-western cluster, the *Setswana* group, and the *Afrikaner* group. The Afrikaner group has only one breed, the Afrikaner breed, which is located primarily in South Africa with a population of 302,000 heads.

The Shona cluster is made of the Mashona cattle breed that is mostly reared in east and central Zimbabwe and estimated at 500,000 heads. The mature weight for Mashona bulls ranges between 350 and 635 kg, while that of mature cows has been estimated at 260–410 kg (Rege 1999) and 275–350 kg (Khombe 2002). The median calving interval of Mashona cows is 548 days (Hall 1998). The cattle are reared for meat and as work animals. The dominant coat colour is black, with secondary colours, including red and various shades of brown. Generally, these cattle are closely related to the other Sanga in the sub-region—that is, Nkone, Tuli, and Nguni (Khombe 2002).

The Nguni cluster: The Nguni group of cattle is considered by some as the 'true Sanga cattle of southern Africa', historically owned by the Bantu (the Nguni people represent a south-eastern Bantu people) on the coast. These cattle descended from the original Sanga that were introduced into southern Africa when the Khoikhoi (Hottentots) and their Sanga cattle first crossed the Zambezi River about 700 AD. The Nguni cattle in South Africa and the Kingdom of Eswatini number about 2.2 million heads. The Nguni cluster is made of four breeds or strains, namely *Landim, Nguni, Nkone, Pedi*, and *Shangan*. The Nguni cattle have a mean weight in male cattle of 400–680 kg and 225–450 kg in females. The cattle are reared for meat, milk, and work (Rege 1999).

The '*Landim'* strain is found in the eastern part of the Kingdom of Eswatini and the Zululand territory of South Africa. In Mozambique, the Landim cattle are kept in areas of the plains of Gaza, in the Inhambane coastal area, and in Maputo Province. Small herds are also found on the northern shores of the Limpopo River near Zimbabwe, where they interbreed with the Mashona cattle (Alberro 1983). These cattle survive on marginal land and are tolerant of local diseases and adapted to a hot environment. Landim cattle have a wide array of coat colours and patterns but stand out as black, white, dark brown, brown, and white (Kotze et al. 2000). The breed is threatened by extensive crossbreeding and replacement with exotic cattle (Bessa et al. 2009). A Landim herd and a heifer are shown in Fig. 4.20, while a typical Nguni bull and cow are shown in Fig. 4.21.

The Zambia/Angola cluster includes the *Tonga* (Zambia) and *Porto Amboim (*Namibia*)*, while another cluster called the '***Ovambo and south-western cluster'*** includes the *Ovambo, Kaokoveld, Okavango, and Caprivi* strains; all of Namibia; and the *Humbi* strain found in Angola.

The Tonga

Distribution and ecological settings*:* The Tonga breed is found in the Southern Province of Zambia, on the Zambezi Plateau, between the

Fig. 4.19 An Abigar bull and a herd of Abigar cattle. (Courtesy: AGTR, ILRI)

Kafue and Zambezi rivers and Northern Zimbabwe, and the valley areas surrounding Lake Kariba. The Tonga breed is named after its owners, the Bantu-speaking Tonga people who inhabit the southern portion of Zambia (and the neighbouring areas of northern Zimbabwe and Botswana). Estimated at more than one million in the early twenty-first century, the Tonga people are concentrated along the Zambezi Escarpment and along the shores of Lake Kariba.

Butonga, the core Tonga area, lies between 16° and 18° S and between 26° and 29° E and is bounded on the north by the Kafue and Sanyati rivers, in Zambia and Zimbabwe, respectively, and on the south by the Zambezi and Gwai rivers. It includes the southern Zambian plateau, which rises to more than 1000 metres above sea level. The Middle Zambezi Valley is known as Gwembe Valley. Mean annual rainfall ranges from 80 cm on the escarpment to 40 cm in northern Gwembe Valley. Drought years are frequent, and rains are expected to start by mid-November, tapering off through March to April, as the cold, dry season sets in. Light frost may be experienced in the June–July period, before the hot, dry season sets in abruptly about late August, with temperatures that can reach 45 °C in northern Gwembe.

The Tonga cattle breed is believed to have been in Zambia even before the Bantu migration from East Africa. Due to the continuous interbreeding with exotic breeds, the original Tonga breed is now concentrated around the valleys of the Zambezi River, where the conditions are unfavourable for the other breeds of cattle (Mwaanga and Parés-Casanova 2017). The breed is made up of a mixture of various ecotypes found in different districts of the province. Because of this variation, Tonga is yet to be registered as a distinct breed with the Herd Book Society of Zambia. Due to its adaptability to the local environment, the Tonga breed is widely used in crossbreeding with exotic breeds to produce crossbred beef and dairy animals. The habitat of the Tonga is no longer limited to the Southern Province of Zambia. It has continued to migrate northwards as the Tonga people move in search of new farming areas. This represents a major threat for the breed through the uptake of commercial cattle breeding, interbreeding with other cattle populations in their new locations, and the impact of East Coast fever in the province. As more people acquire high-producing exotic bulls at the expense of local Tonga bulls that are deemed inferior, the indigenous Tonga is gradually being replaced through upgrading. Rege (1999) reported a population estimate of Tonga cattle at 993,000.

Physical characteristics: The differences between the ecotypes found in the different districts make the breed quite heterogeneous phenotypically. Generally, Tonga cattle have a small body size and short-to-medium-sized horns that spread outwards from the head (Musimuko 2014). The coat colour is variable, ranging from pure black to white, but brown tends to dominate in most herds, especially those found on the pla-

Fig. 4.20 A Landim cattle herd and a heifer in Mozambique. (Courtesy: Maria da Gloria Taela)

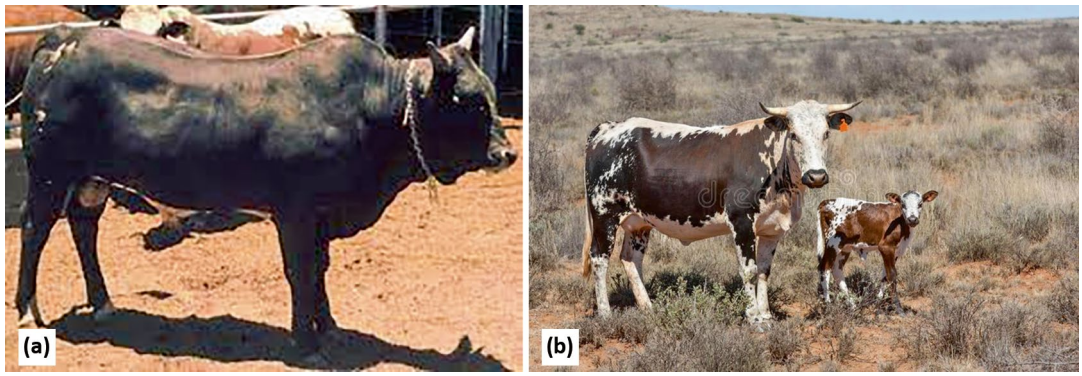

Fig. 4.21 A typical Nguni bull (**a**) and a cow with a calf (**b**). (AGTR, ILRI)

teau areas of Sinazongwe and Maamba. The ecotypes found in the valleys tend to be relatively larger than those found on the plateau. One ecotype found on the shores of Lake Kariba in Kalomo District is locally referred to as the Mazambezi and is considerably larger than the upland strains. A herd of Tonga cattle is shown in Fig. 4.22.

Uses and production characteristics: The Tonga is mostly kept for meat, although, as is common among pastoral communities, the Tonga people will rarely slaughter an animal for food or sale unless there is a funeral or wedding in the family. Because of its small body stature, the Tonga breed is not well-adapted as a work animal. However, nearly all farmsteads have a set of working animals that are used for ploughing and the transportation of produce to and from markets.

Adaptive or special genetic characteristics: Due to its adaptability to the local production environment, the breed is widely used in crossbreeding with exotic breeds to produce crossbred beef and milk animals.

The members of ***the Setswana group*** are the *Barotse, Damara (Herero), Tswana*, and the *Tuli* cattle. These are summarized below.

The Barotse Cattle

Distribution and population statistics: The homeland of the Barotse cattle is Barotseland of the West Province of Zambia and the Kalahari and Namib Deserts in the neighbouring Angola, Namibia, and Botswana. The territory is characterized by the floodplain of the Zambezi, extending into Angola on the west. The breed is kept principally by the Lozi people living on the Zambezi floodplain and is also known as Lozi,

Rowzi, Rozi, or Baila. The Barotse population appears to have expanded after the rinderpest epidemic (Felius 1995). There are a number of strains of the Barotse from the various districts: the Shang'ombo strain—more closely related to populations in Angola—tends to be relatively larger than the Kalabo and Lukulu types. The Barotse population has been estimated at 793,000 (Rege 1999), and the population in Zambia has been estimated to be less than 100,000 (DAD-IS 2005). The majority of this breed is found in Angola. High mortality caused by contagious bovine pleuropneumonia (CBPP) and the effects of indiscriminate crossbreeding and drought are the major risk factors for the breed.

Physical characteristics: The Barotse has typical Sanga conformation with long horns and legs; they are coarse-boned and have a large, long appearance due to their long legs (Felius 1995). The main distinguishing features of Barotse cattle include the large, long but relatively slender body frame with long lyre-shaped horns that spread and curve backwards (Musimuko 2014). Despite the large body frame, it is rare to see a fat, well-rounded Barotse animal.

The coat colours are usually brown, dark red, fawn, or black, sometimes mixed with white. White or brown patches on the sides and under the belly are not uncommon. Pure white colour has not been reported. The Barotse hump is small, often barely visible in the cow. The height at withers of mature male and female animals are 120–137 and 114–129 cm, respectively (Mason and Maule 1960). The hump is small in males and barely visible in cows. A herd of Barotse is shown in Fig. 4.23.

Production characteristics and uses: Barotse cattle are used as beef and milk animals, and the sour milk made from Barotse cow milk (the *Muzilili*) is known for its special taste and flavour. However, beef is the most important product. The animals are docile with good temperament, and hence, the bulls are good work animals. Under good management, they weigh between 485 kg (for females) and 700 kg (for bulls), compared to weights of 400 kg for females and 580 kg for males under average management. The age at first calving is about 44 months, while the lactation milk yield is 1077 litres in an average lactation length of 302 days. A conception rate of 67% and a calving interval of 620 days have been reported (Thorpe et al. 1981).

The Baila

There is debate on whether the Baila of the Kafue floodplains in the Southern Province of Zambia is a separate breed or not, and despite having distinct features, the Baila is generally considered to be an intermediate crossbreed between the Barotse and Tonga cattle breeds. It is not among the recognized breeds of cattle in Zambia. This could be because it only accounts for about 1% of the cattle population in the country (Kaluba 1984). They are mainly found along the Kafue floodplains in the Mumbwa and Namwala districts of Zambia. The animals have a relatively large bone frame. Their large horns are similar in shape but shorter than those of the Barotse breed and longer than those of Tonga. They have a clearly defined cervical hump. It is a meat breed. The animals have good heat tolerance and disease resistance abilities (Mwaanga and Parés-Casanova 2017).

Tswana or Setswana Cattle

Distribution and population statistics: It is considered that the Tswana people settled with their livestock in the Ngami region of Botswana early in the nineteenth century and that, over time, their cattle displaced the original Ngami cattle (Rege and Tawah 1999). Today, Botswana is the epicentre of the Setswana cattle, and the most typical Tswana cattle occur mainly in the north and north-west of Botswana in Ngamiland and along the Boteti River. Tswana-type cattle extend into the south-western Zimbabwe. In South Africa, they were originally found in the Northern Cape of Transvaal. The population of Tswana cattle in Botswana was reported at 1.4 million heads by Rege (1999). No estimate is available on the population size of the breed in South Africa and Namibia. The purity of the Tswana breed is declining due to crossbreeding with the Brahman and exotic (European) breeds (DAD-IS 2005). Other names used locally for the breed include Bechuana, BataWana, Mangwato, Sechuana, Seshaga, and Sengologa.

Fig. 4.22 A herd of Tonga cattle. (Courtesy: DAGRIS, ILRI)

Fig. 4.23 A herd of Barotse cattle. (Courtesy: Dr. Denis Lembani)

Physical characteristics: Today, the Tswana cattle are quite phenotypically heterogeneous. Typically, they have long, lyre-shaped horns, but dehorning is a common practice, especially on commercial farms. The Tswana are well-built and well-fleshed, with moderate to long legs. They are multicoloured with colour patterns of black, brown, grey, and white, the typical ones being red and red and white. A herd of Tswana cattle is shown in Fig. 4.24.

Production characteristics and uses: Tswana cattle are mainly used for beef, milk, and draught power. Their beef is considered to be of high quality. They are fertile, and the females are known for their ease of calving, and the quality of hides is good. Calving percentage is 70–81%. The average age at first calving is 36–48 months, and the calving interval is 18–24 months in traditional herds. The Tswana outperforms other South African breeds including Tuli and Afrikaner in growth traits, but the breed has lower growth rates than the Bonsmara and its crossbreeds. The mature weight of male animals is 310–520 kg and that of females is 290–420 kg (DAGRIS 2022). The average daily milk yield of a Tswana cow is 1.4 kg. They are used for crossbreeding with the exotic dairy and beef bulls for improved milk and meat production. Calf mortality is about 7.5%.

Adaptive or special genetic characteristics*:* The breed is known to have a high level of tick and heat tolerance and is adapted to dry and hot environments.

Damara or Herero Cattle The Himba, a Herero-speaking people, settled during the sixteenth century in North-western Namibia with their Sanga cattle. Today, this area is known as Kaokoland. The Himba have a nomadic lifestyle and roam freely in search of water and grazing for their livestock. Although the Herero primarily reside in Namibia, there are also significant populations in Botswana and Angola. Not much has been done to document the unique characteristics of the Herero/Damara cattle that differentiate them from the neighbouring Sanga cattle.

The Tuli

Distribution and population statistics: Originally called the *Amabowe* cattle of Ngwato Setswana type in the south-west corner of Zimbabwe, an area stretching from Tuli to Plumtree, the rinderpest epidemic of 1896 reduced the number of these cattle substantially. Much of what was left was crossed with the Afrikaner cattle. Remnant herds of the original population were restricted in the Tuli area; hence, the present-day name of the breed. Today, the Tuli is distributed in several countries in the region, especially in the neighbouring Botswana and South Africa. It has been used in forming the synthetic breed *Akouma* in Gabon. It has also been exported from Zimbabwe to Australia, the United States, and Canada (Rege and Tawah 1999; Mpofu 2002). The Tuli cattle population in the national commercial herds is about 10,000 in Zimbabwe and 2339 in South Africa (DAD-IS 2005). There are seven stud farms in Zimbabwe, and excess bulls from these farms are used in many commercial farms in the country. There is no estimate available on the number of Tuli cattle held by smallholder producers. However, the existence of a breed society and sustained efforts to improve the breed and popularize it internationally have significantly reduced the chances that the breed could be endangered.

Physical characteristics: The Tuli is a medium-sized 'pure African Sanga' breed and is one of the few that has benefitted from organized breeding: The Tuli breed society was formed in 1961, and several stud breeders are operational in Zimbabwe (Mpofu 2002). The Tuli is a heavy-boned animal with long, wide, spreading horns and long, strong legs. The coat colour is mostly red, red and white, and golden brown. The Tuli have been selected for their golden brown colour and with selection preference for polled animals, and selection against shyness and poor breeding. A Tuli herd and bull are shown in Fig. 4.25.

Production characteristics: The Tuli breed are characterized by a high calving percentage of 70.6%, mortality between birth to 2 years estimated at 7.5%, and a weight at 18 months of age of 284 kg. The Tuli cattle are good beef animals. Weights at birth, at 90 days old, at weaning, at the age of 18 months, and at 5.5 years were 31.9 kg, 105.8 kg, 189.7 kg, 284.1 kg, and 411.1 kg, respectively (Ward and Tawonezvi 1983).

Adaptive or special genetic characteristics*:* Today's Tuli cattle are characterized by high fertility, early maturity, hardiness, adaptability, ease of calving, good mothering ability, good carcass characteristics, and docility (Assan 2011).

The Afrikaner

Distribution and population statistics: The Afrikaner cattle are believed to have been brought to the present-day South Africa by the Khoikhoi people during the first century AD. The Hottentots owned large herds of Sanga-type cattle when the Dutch established the Cape Colony in 1652. The oxen drew the wagons, which carried Boer farmers and families on the Great Trek of 1835–1836 from the Cape of Good Hope to the Orange Free State, Natal, and the Transvaal to escape British rule. The present-day breed was developed from these original Hottentot cattle in Cape Province. Today, the breed is the most popular indigenous breed in South Africa (Maule 1990), being bred throughout the country, the main ones being North-east Cape, Orange Free State, Transvaal, and West Natal. The Afrikaner cattle have been exported to several countries in and outside Africa, including Namibia, Botswana, Swaziland, Zimbabwe, Zambia, Malawi, the Democratic Republic of the Congo, Australia, and the United States (Rege and Tawah 1999).

Physical characteristics: The Afrikaner coat colour ranges from dark to light red. The hump is

Fig. 4.24 A herd of Tswana cattle. (Courtesy: ILRI)

prominent but not large and is cervico-thoracic. The long spreading horns leave the head in a downward and backward direction and then, at maturity, bend gracefully forwards, upwards, and backwards. Through breeding, a polled type of Afrikaner has also been developed. Typical Afrikaner bulls are shown in Fig. 4.26.

Production characteristics and uses*:* The breed was developed as a draught animal (or *trek ox*), and it is only in the past half century or so that its beef potential has been exploited. It is among the largest breeds in Africa, with birth-weights of male animals being about 33 kg. Adult bulls weigh 450–950 kg, with an average of 745 kg, and adult cows weigh 360–555 kg (average 525 kg). Weights of up to 1100 kg have been recorded in show animals (Rege and Tawah 1999). The age at first calving is about 36 months, and the calving interval is about 445 days. Calving percentages are highly variable and are lower than those of other indigenous breeds, e.g. Tswana, Tuli, Angoni, and Mashona.

Adaptive and special genetic characteristics*:* The legs of the Afrikaner are slightly sickle-shaped. The animals have good resistance to tick-borne diseases and are well-adapted to the local hot, arid conditions: the sweat glands in their skin are reportedly more active than those of taurine cattle, and this makes them more tolerant of heat than the European breeds.

4.2.3 The Pseudo-Sanga of West Africa

A distinction must be made between the general cattle group ‘Sanga’, which is used to mean the long-term, established Zebu × Taurine derivatives represented by several breeds in eastern and southern Africa (Sects. 4.2.1 and 4.2.2 above) and the more recent West African Zebu × Taurine crossbreeds described in this section. Even though we have classified the West African recently stabilized Zebu × Taurine crosses as Sanga here, to avoid attendant confusion, the use of *pseudo-Sanga* in reference to the more recent Zebu × humpless crossbred populations is advised. Pseudo-Sanga is used to connote two things: the first is to emphasize the heterogeneity of the genotype compositions of these populations, which are constantly changing as the cross-breeding processes continue, and the second is to distinguish these dynamically evolving populations from the Sanga of eastern and southern Africa, which are more stabilized and some of which are registered as unique, commercial breeds. Table 4.4 summarizes the breeds/strains of the present-day *pseudo*-Sanga cattle populations of West Africa, indicating the parental breeds from which they were (and are being) derived, and the countries with major populations of the breeds/strains (Rege 1999). The major

Fig. 4.25 A Tuli herd and a bull. (Courtesy: Tuli Cattle Society of Southern Africa)

groups/clusters of the pseudo-Sanga of West Africa are described below.

The Evolving Pseudo-Sanga Strains

The Sanga of West Africa include the ***Borgou, Méré, Ghana Sanga, and Keteku*** (or ***Borgu***). Earlier reports (e.g. (Doutressoulle 1947; Flamigni 1951)) used the term ***Borgu*** to refer to all forms of humpless × Zebu cattle crossbreeds in this region. In reference to crossbreeds of this type (Doutressoulle 1947), stated that '*…these same animals are encountered in the corresponding regions of the neighbouring Togo, Nigeria, Ivory Coast (**Méré-Lobi**), with small differences due to environment and* selection'. The same report states that the Borgu is known by different names such as Borgowa, Kettije, Ketaku, Keteku, Ketari, and Kaiama. Epstein (1971) states that '*... the general conformation of the body as well as the occasional occurrence of relatively long horns in the Borgu indicate the influence of White Fulani and possibly N'Dama Longhorn blood*' and that '*... in Western Nigeria, this type of cattle, called Keteku, is derived from a mixture of the humpless Dwarf Muturu of the south and the Zebu of the north'*.

The definition of Keteku has become more problematic in recent years, with an increasing proportion of Zebu blood in 'Keteku' herds. As Fulani pastoral herds push even further south and increasingly inhabit regions previously restricted to trypanotolerant stock, more Zebu stock are brought into these herds from village Zebu herds. For example, the 'Biu', a Zebu × Savannah Muturu cross found near Biu in southern Borno (e.g. (Gates 1952)), has effectively become submerged in the local Zebu gene pool. Thus, the application of the name Keteku to an individual animal may reflect as much the owner's cultural background as its actual genetic composition. The population size of Keteku in Nigeria was 180,000 heads (ILCA 1979a). Keteku are significantly less common than previously thought, and their distribution is quite different. It is unlikely that there are as many as 100,000 of all types. The distribution and productivity of **Keteku** cattle have been studied in more detail (Blench et al. 1998).

Epstein (1971) also recognizes the ***Biu*** of the Bornu State of Nigeria as a type similar to the Borgu but smaller. Gates (1952) states that the Biu is the result of White Fulani crossbreeding with the humpless Dwarf Shorthorn. Mason (1988) and Maule (1990) recognize the Biu as a distinct breed; however, Mason (1988) and ILCA (1979a) observed that the Biu has been absorbed by Zebu. The general consensus is that the Biu, when it existed, differed from the Keteku as it is known today: the Keteku is a broader mixture of Zebu (mainly White Fulani) crosses with N'Dama and/or Shorthorns, while the Biu was more specifically defined as a cross derived from White Fulani and Dwarf Muturu. Reference has also been made to the characteristic long horns and white with black colour markings of the Biu (Epstein 1971; ILCA 1979a). Today, large num-

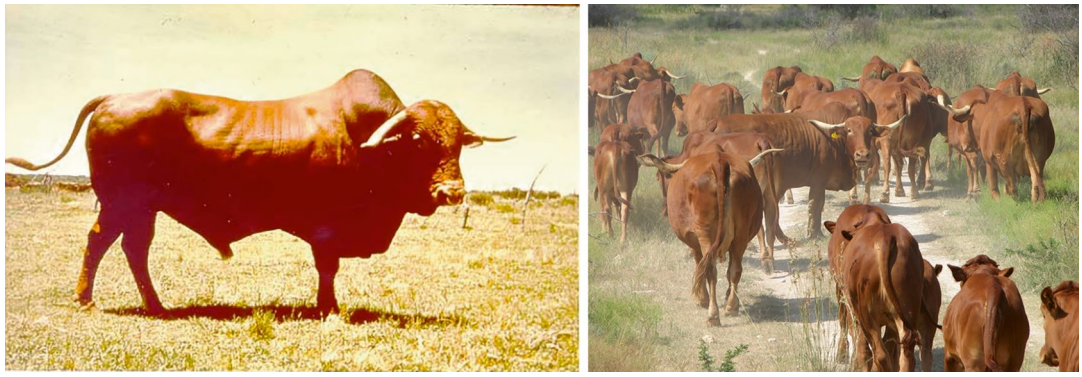

Fig. 4.26 Afrikaner bull and herd. (Courtesy: Afrikaner Cattle Breeders' Society of South Africa)

Table 4.4 The pseudo-Sanga of West Africa[a]

Breed/ strain	Parental breeds/ strains	Country	Population[b]
Borgou	Zebu × Somba or Lagune	Benin, Togo	380,000-580,000
Méré	Zebu × Lobi or Baoulé (and N'Dama)	Burkina Faso, Côte d'Ivoire	600,000-700,000
Ghana Sanga[c]	Ghana Shorthorn × Zebu	Ghana	120,000-125,000
Keteku	Muturu × White Fulani, 'Borgu', Kaiama	Nigeria	100,000-300,000
Biu	Dwarf Muturu × White Fulani	Nigeria	NA

[a]'Pseudo-Sanga' is suggested here to distinguish the West African group, which is more recent, still highly variable, and under development, from the more established Sanga breeds of eastern and southern Africa, which are largely recognized as distinct breeds
[b]From Rege (1999)
[c]Occasionally N'Dama × Zebu crosses; Zebu used is principally White Fulani but occasionally Sokoto Gudali

bers of Keteku are found in Kwara State of Nigeria, where they are thought to be an extension of the Borgou population of Benin.

ILCA (1979b) points out the difficulty of identifying a standard type of the Borgou breed in Togo since all intermediate types between the humpless breeds and Zebu are commonly grouped under this name. However, the same report defines the Borgou in Benin as a cross between Zebu (mainly White Fulani) and West African Shorthorn (Somba or Lagune). The ***Méré***, like the Togolese ***Borgou***, refers to a whole range of crossbreeds between Zebu and humpless breeds (including the N'Dama) in both Burkina Faso and Côte d'Ivoire. In Burkina Faso, the Méré is found mainly in a belt from the west to the east, including Bobo Dioulasso and Koudougou, which widens parallel to the southern border, south of Koupela and Fada N'Gourma. In Côte d'Ivoire, there is little information about the Méré crossbreeds or their numbers, although crossbreeding is extensively practised in the North. Figure 4.27 shows a typical Keteku cattle herd.

The Ghana Sanga is a cross between Zebu and Ghana Shorthorn. The Zebu breed involved is commonly White Fulani, but occasionally, Sokoto Gudali is used. Similarly, the N'Dama occasionally replaces the Ghana Shorthorn in the cross. The term is also used to include similar crosses involving the Dwarf Shorthorn. The Ghana Sanga resembles the Shorthorn type more closely than it does the Zebu, but, like the Zebu, it is found in the drier areas of the country towards the northern border and on the Accra Plains, extending into the Volta Region.

In addition to the above stabilized crosses, there are other Zebu × Taurine (mostly N'Dama) crosses in the region. These include the ***Djakore*** or ***Djokore*** of Senegal, ***Bambara*** (also known as ***Méré***) of Mali, and various gradations of Zebu × N'Dama crosses in Guinea, the Democratic Republic of the Congo, The Gambia, and Gabon. In the Central African Republic, these crosses are also called Bambara. Maule (1990) defines the

Bambara as a '*variety of N'Dama with Zebu blood'*. Other than in Mali and the Central African Republic, the name ***Borgou*** is widely used to refer to various strains of Zebu × humpless crossbreeds in French-speaking countries. In Ghana (Sanga) and Nigeria (Keteku and Biu), more specific names are used. In all cases, however, care needs to be taken to ensure that, as much as possible, a population ('breed' or 'strain') in question is accurately defined in terms of its composition and location.

Production systems: As alluded to above, there are four broad types of Zebu × Taurine (mostly Shorthorn) crossbreeds: the *Méré* in Côte d'Ivoire and Burkina Faso, the *Ghana Sanga* in Ghana, the *Borgou* in Togo and Benin, and the *Keteku* (or *Borgu*) in Nigeria. The common environment of these populations is the intermediate Sudanian zone between the Zebu-dominated north and the tsetse-infested south, which provides the greatest opportunity for interbreeding between the two groups. This is an important agricultural area, producing groundnuts, cotton, and sorghum. Farming is intensive, and the livestock density has traditionally been high. Livestock are confined to fallow land or areas unsuitable for cultivation during the rainy season. In the dry season, animals are left to graze freely, and crop residues, mainly cereal straws and groundnut haulms, make important contributions to their diet. Fodder is not usually grown, but there is an abundance of groundnut stalks and standing hay. When the cattle owners or herders are Fulani, the animals are managed in a similar way to any Fulani herd. Draught animals are widely used to pull carts and ploughs in many of these areas, such as Sine Salown in Senegal, southern Mali, southern Burkina Faso, and the province of Borgou in Benin. Cattle are also used for manuring fields by letting animals feed on crop residues in the field. In some areas, animals are tethered in the fields. Herds are often large, and the proportion of males in the herds is high (28–32%).

Physical characteristics: These populations, being unstabilized crosses in which the injection of new genetics continues, exhibit considerable variations in size, conformation, and colour markings. The Keteku and the Borgou are generally very similar, although their sizes usually vary with the amount of Zebu breeding. In Nigeria, for example, the Keteku is larger and taller in the northern Guinea savannah than it is in the southern Guinea savannah. Likewise, in Benin, the Borgou varies in size from the small 'true' Borgou of the south to the large Borgou–Zebu of the north. In body conformation, the Keteku is of fair depth, although it is inclined to lack width at the chest and to be flat over the ribs. The Borgou has an elliptic and compact body with a straight profile, while the Ghana Sanga and Borgou–Zebu have similar conformations as that of the Zebu (Domingo 1976). The head of the Keteku is generally well-proportioned, straight, and 'dished' in profile, while that of the Ghana Sanga has a long, straight, and convex profile. The head of the Borgou is generally triangular and thick at the extremities, but it is long with a flat forehead among the small Borgou. Horns are of medium length in the Méré, but in the Ghana Sanga, they are long and U-shaped, as in the Bunaji. The necks of both the Borgou and Ghana Sanga are short and sturdy. The neck of the Borgou is thick and robust in the males and skinny in the females, and the neck of the small Borgou is very muscular around the shoulders as well. The top line in the Keteku slopes up to the sacrum, with the rump tending to slope steeply between the hooks and the pin bones. The top line of the Borgou is generally not straight, and the rump is short. The top line of the small Borgou is straight, with a long and narrow back. In contrast, the back of the Ghana Sanga is short and concave, like that of the Borgou–Zebu, with an elevated rump. The hump is rudimentary and usually inconspicuous in these populations. It is cervically positioned in the Keteku, but with increasing White Fulani breeding, the hump tends to be larger and cervico-thoracically positioned. The dewlap and umbilical folds are retracted and poorly developed in the Keteku, although they are better developed in the Borgou–Zebu, depending on the degree of Zebu breeding. The chest of the Borgou is particularly deep in the males, and it is very solid in the Borgou–Zebu, which has a short and robust body. The hindquarters of the Keteku are poorly developed,

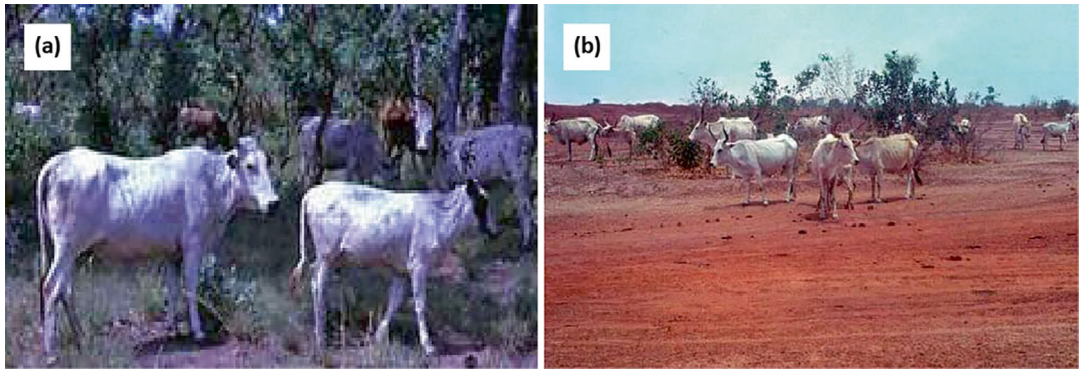

Fig. 4.27 Typical Keteku (**a**) and Djakore (**b**) cattle herds. (Courtesy: AGTR, ILRI)

with the thighs lacking in width and fullness, although it has a broad hip (40 cm in males and 39 cm in females). The tail-head is set high, and the legs are averagely long, with light and fine bones. The small Borgou has short legs, and the females have well-developed udders. Coats are similar in colour markings and patterns in the Keteku, Borgou, and Ghana Sanga, but considerable variation exists within each of these populations, with pure white being the dominant colour, while black is the most common in the Ghana Sanga and white with black spots and black markings in the Keteku and Borgou. Solid black or black and white or spotted grey or fawn coats are also evident in the Borgou. A variety of other colours, including black, black and white, faded red, red and white, or blue tinge, also exist in the Keteku. Méré cattle have mostly typical pure black coats, although black and white or brown and white coats are also common.

Adaptive and special genetic characteristics*:* The Keteku is more susceptible to trypanosomosis and dermatophilosis than the N'Dama and the Muturu in the same locality, but, like the Ghana Shorthorn, it is more tolerant than the White Fulani or the Gudali. Borgou cattle, like the Keteku, are adapted to the harsh conditions of production and are tolerant of trypanosomosis. Some studies (e.g. Doko (1993) and Dehoux and Hounsou-Ve (1993)) have demonstrated that the Borgou has trypanotolerant attributes that are similar to those of the Lagune and N'Dama but with a higher degree of within-breed variation.

Production characteristics: Birthweights of Borgou calves are slightly lower than those of the Keteku under ranch conditions. Birthweights of the Méré calves on-station in Burkina Faso have averaged 18 and 17 kg, respectively, in males and females. Corresponding weights at weaning (about 8 months of age) have averaged 128 and 112 kg. The Keteku cattle raised on a ranch in Nigeria with heavy tsetse challenge had a higher growth performance than the Borgou cattle raised on a ranch in Benin with light tsetse challenge. This points to a greater tolerance to trypanosomosis of Keteku than Borgou cattle. Mature weights have also varied considerably across breed types. Typical mature weights have ranged from 190 to 280 kg for the Borgou cattle in Benin, from 295 to 330 kg for the Keteku cattle in Nigeria, and from 260 kg for the Méré cattle in Côte d'Ivoire to 320 kg for the Ghana Sanga cattle (ILCA 1979a). In these systems with limited animal recording, the considerable variation in mature weights may reflect the lack of knowledge of precise age at maturity. However, in general, these stabilized crosses are heavier at maturity than their humpless parental stock but lighter than their humped parental stock. The age at first calving in the Borgou cattle in Benin has ranged from 43 months in sedentary village herds to 46 months in transhumant herds, averaging 43.5 months, and has varied from 38 to 47 months for the Keteku cattle under ranch conditions in Nigeria and from 48 to 60 months for the Méré cattle under village conditions in Burkina Faso. The mean calving intervals for the Borgou cattle

in Benin have ranged from 15 months under sedentary husbandry to 18 months under transhumant husbandry and averaged 16 months. Corresponding figures for the fecundity rate were 64 and 67 per cent, with an average of 65 per cent. Surprisingly, reproductive performances under these different systems of production reported in the literature have tended to be quite similar, which does not support the suggestion by Wilson (1988) that transhumant herds are relatively better nourished and, therefore, are expected to perform better than sedentary herds. The mean calving intervals have varied from 15 to 20 months in Borgou cattle and from 18 to 24 months in Méré cattle under village conditions. For Keteku cattle, they have ranged from 16 to 19 months under ranch conditions. The calving rate in the Borgou cattle in Benin has ranged from 33 to 75 per cent under ranching management at M'Betecoucou, a location characterized by light tsetse challenge (ILCA 1979a, b; Lopez 1985), and from 40 to 67 per cent under village conditions (Dehoux and Hounsou-Ve 1993). These differences may partly be the result of variations in the levels of trypanosomosis challenge. The bimodal calving frequency in village herds in Benin (ILCA 1979b) is an indication that the breeding in Borgou herds is seasonal in character, which is a direct effect of nutrition on the fertility in traditional village herds. In addition (Dehoux and Hounsou-Ve 1993), reported that about 45 per cent of the Borgou herds in Benin have only one young breeding bull. Since young bulls can only breed 30 cows per year at most, the herd fertility is bound to suffer in these systems where herd sizes are large. Other factors contributing to the poor fertility of Borgou cows in the village herds in Benin are prolonged suckling, trypanosomosis, brucellosis, and other infectious diseases.

Population sizes: While this chapter does not put emphasis on the population sizes of the breeds covered, the dynamism in population sizes of West African cattle breeds, especially the rapid interbreeding between Zebu and Taurine types and the consequences of this, requires special mention. Population sizes and trends are discussed in Chap. 3. As pointed out in Sect. 3.4 of that chapter, the stabilized crosses require systematic characterization, with a focus on gathering both phenotype and genotype data on the production and adaptive traits of these new 'breeds' or 'strains' relative to those of the parental types, as part of a process to determine the attributes to define the end point of the envisioned new breeds and breeding plans towards genetic stabilization.

4.3 The Zenga Cattle

The 'Zenga', a term introduced by Rege (1999), refers to the cattle derived from the interbreeding between Sanga and Zebu cattle. The Zenga is heavier than the Zebu but lighter than the Sanga (Kajura 2001). Exclusively located in eastern Africa, some members are found in predominantly the Zebu habitat and others in the Sanga habitat. Indeed, the location of Zenga forms a natural division between the Zebu country in the north and the predominantly Sanga country in the south of the African continent. The members of the Zenga, a total of eight, are the Arado, Fogera, and Horro (of Ethiopia); Jiddu (southern Somalia); Alur, also called Nioka (Nyoka) or Blukwa cattle (the Democratic Republic of Congo), derived from crossing Ankole cattle with Small East African Zebu in the area (that is, Lugware and Nkedi); Nganda (Uganda); Sukuma (Tanzania); and Bovines of Tete (Mozambique). Table 4.5 presents a summary of the classification of the present-day Zenga breeds/strains of eastern Africa. They are briefly described below.

Arado Cattle

The Arado cattle are red- and black-coated and are small-bodied and hardy. They are the most common cattle variety in the north Ethiopian highlands, where the breed is reared mainly for draught power. Closely related to the Arado are the Abergele cattle, which are the smallest breed of north Ethiopia in the Abergele lowlands and at the south-western lower slopes of Dogu'a Tembien district. The Abergele ecotype is known for its adaptation to the hotter and drier lowlands, is tolerant of diseases and parasites, and can cope

with feed shortages during long dry periods. Another closely related Zenga ecotype is the Begayt, which is currently being crossed with the Arado to increase the milk production of the Arado.

Fogera Cattle

The Fogera breed (Fig. 4.28) is found in the Fogera Plains, which lie to the east of Lake Tana, covering the area around the town of Woreta, between Bahir Dar and Gondar in Ethiopia. The area is a flat, open plain, across which the Rib River flows into Lake Tana, with the Gumera River forming the southern boundary. Among the typical characteristics of the Fogera cattle are the broad hooves, which allow it to move more easily in the marshes of the Fogera Plain. The breed is highly tolerant of heat stress and solar radiation and is also known for its tolerance to high altitudes, parasite and disease infestation, fly burden, wet soils, and swampy areas. The Fogera is considered at risk, and conservation interventions are being taken.

Horro Cattle

Also known as Wallega or Wollega cattle, the habitat of the Horro breed (Fig. 4.29) is the Horro Guduru Welega Zone of western Ethiopia. The population of cattle in the Horro area was estimated to be around 47,700 heads in 2017 (Mekonnen et al. 2021). The breed is mainly used as a draught animal and for milk production. The Horro have a large body size, small-to-medium hump size, small dewlap, fine skin, and uniform brown colour, which is lighter around the muzzle. The adaptation to their environment and the relative resistance to trypanosomosis disease make the Horro an important breed in its habitat.

Nganda Cattle

The Nganda, also known as Sese Island cattle, is a Sanga–Zebu intermediate, which was developed as a result of interbreeding the East African Shorthorn Zebu and the Ankole and the Alur cattle (Rege and Tawah 1999). It occupies Central Uganda and parts of Western Uganda, south of Lake Albert (Kajura 2001). The Nganda was developed mainly from the interbreeding of the Small East African Zebu in Uganda, mainly the Nkedi, and the Ankole Sanga (mainly the Baima but also Watusi in recent times). Indeed, the Ankole cattle have been mixed with the adjacent Bukedi Zebu over the past three centuries (Rege and Tawah 1999), and the interbreeding continues. Although it is not currently on the red or yellow list of threatened breeds, the Nganda deserves conservation attention. The only on-station open nucleus breeding herd for the breed in Uganda was disbanded and is being considered for reconstitution.

The Nganda breed habitat is the Buganda region in central Uganda and, hence, the name Nganda. In the area north of Lake Victoria and between Lake Kyoga (Busoga region), it is referred to as Nsoga type, and in the areas around Lake Albert (Bunyoro region), it is called the Nyoro type. This breed of cattle is also found in the tsetse-infested areas south of Lake Albert and east of Semiliki River. The bulls have characteristic wrinkles around the eyes.

The special characteristics of Nganda cattle are horns that are typically long and round in cross section and white and thick at the base; a hump that is small and cervico-thoracic in location; and the dewlap that varies but is generally moderate in size, sometimes appearing a little fleshy but has few folds. The coat colours are variable, with red, black, and brown being more common.

Nganda are used for milk and work and as meat animals (Rege and Tawah 1999). The adult body length of male Nganda cattle ranges between 283 and 416 cm, that of the female range between 300 and 338 cm, and the height at withers in male Nganda averages 116 cm and 115–122 cm in females. The Nganda cattle are hardy and have high reproductive rates, even under poor nutrition. On average, they produce a calf every year (DAGRIS 2022). A typical Nganda cow is shown in Fig. 4.30.

Sukuma Cattle

Sukuma cattle are a product of the interbreeding of various ecotypes of Tanganyika Zebu with the Ankole from adjacent areas of Rwanda, Burundi, and southern Uganda. The current habitat is lim-

Table 4.5 Zenga (Zebu–Sanga) cattle, recent derivatives, and synthetic breeds

Group and breed/ strain	Location/ country	Mature weight (kg)		Withers height (cm)		Main uses (in the order of importance)
		Male	Female	Male	Female	
1. Zenga (Zebu × Sanga) cattle						
1. Arado	Eritrea, Ethiopia	205–430	192–350	117–144	96–126	Work, milk, meat
2. Fogera	Ethiopia			110–145	100–121	Work, milk, meat
3. Horro	Ethiopia	320–480	210–400			Work, milk, meat
4. Jiddu	Somalia	340–590	325–430	109–133	108–124	Milk, meat
5. Alur (Nioka, Blukwa)	DRC	290–550	225–380	110–131	108–122	Milk, meat, work
6. Nganda	Uganda	280–420	200–340	115–124	115–122	Milk, meat, work
7. Sukuma (Tinde)	Tanzania	230–410	210–370	94–132	93–127	Milk, meat
8. Bovines of Tete	Mozambique					Meat, milk, work
2. Recent derivatives						
1. Borgou	Benin, Togo	190–330	180–295			Meat, work, manure
2. Méré	Burkina Faso, Côte d'Ivoire					Meat, work, manure
3. Ghana Sanga	Ghana					Milk, meat, work, manure
4. Keteku	Nigeria					Meat, work, manure
5. Djakore	Senegal					Milk, meat, work, manure
6. Biu	Nigeria					Meat, work, manure
7. Basuto	Lesotho					Work, meat, milk
8. Barra do Caunzo	Angola	370–620	360–500			Meat, work, milk
9. Rana (Omby Rana)	Madagascar					Milk, meat
3. Systematic synthetics/ composites						
1. Drankensberger	South Africa, Swaziland					Meat, work, milk
2. Bonsmara	South Africa					Meat
3. Renitelo	Madagascar	420–655	305–450			Meat, work
4. Manjan'i Boina	Madagascar					Milk
5. Mpwapwa	Tanzania	360–620	290–455			Milk
6. Wakwa	Cameroon					Meat

Source: Rege (1999)

ited to Tanzania's Sukumaland—south of Lake Victoria on the eastern border of Mwanza and the north-eastern parts of Shinyanga. The area covers Seke, Lalago, Nyalikangu, and the upper Semu River. The horns of Sukuma cattle are medium-to-long and crescent-shaped. They have small humps, small dewlap with thin skin, and a coat colour that varies between red, grey roan, light dun, and solid red. The animals are mainly used for milk and meat but also for work (Rege and Tawah 1999).

Bovines of Tete

Bovines of Tete (Fig. 4.31) were developed from the interbreeding of the Angonia Zebu and the Landim Sanga in Mozambique. Their habitat is the coastal area of northern Mozambique between Lake Malawi and the Indian Ocean. They are considered to have some level of trypanotolerance. They are primarily used for meat but also for milk and work (Rege and Tawah 1999). They are morphologically similar to the Landim but are smaller in size and have larger humps and lateral black horns. They can produce carcasses weighing 85–110 kg.

4.4 Commercial Composite Breeds

Sub-Saharan Africa (SSA) is home to at least five commercial composite breeds with varying proportions of exotic blood. Unfortunately, only one of them—the Bonsmara of South Africa—is secure in terms of numbers and the existence of programmes for continuing genetic improvement. The other four are the Mpwapwa of Tanzania (dual-purpose); the Mangan'i Boina of Madagascar (a dairy breed); the Renitelo, also of Madagascar (beef); and the Wakwa of Cameroon (beef). These breeds are summarized below (see also Rege and Tawah 1999).

The Bonsmara

The Bonsmara breed (Fig. 4.32) is a composite breed of cattle known for high-quality beef. Originating in South Africa as a scientific experiment of Professor Jan Bonsma, the breed was created from the mating between local Afrikaner cows and the European Shorthorn and Hereford bulls, with the final breed composition being approximately 5/8 Afrikaner, 3/16 Shorthorn, and 3/16 Hereford. The outcome of this scientific experiment is a breed that incorporates the hardiness of the Afrikaner and the beef traits of the European Hereford and Shorthorn cattle. The breed's name was coined from the researcher's name, Bonsma, and the research station, Mara. The breed was recognized in 1964, and the Bonsmara Cattle Breeders' Society of South Africa was founded the same year, and breed improvement programmes have been operating since then. The breed was registered in 1972. The Bonsmara has become the biggest of all beef and dual-purpose breeds in South Africa through concerted research undertaken to improve the breed. Bonsmara cows have excellent mothering ability under diverse environmental conditions and wean calves that are suitable for finishing on pasture or in feed-lots and have excellent meat qualities. The animals are well-adapted to warm bushveld and subtropical areas. They are also reported to be tolerant of ticks.

The Bonsmara has been exported to countries in and outside Africa where it has become well-established. Today Bonsmara is found in Zimbabwe, Namibia, Zambia, Swaziland, Botswana, Angola, Mozambique, Rwanda, the Democratic Republic of Congo, Australia, Argentina, Paraguay, Brazil, Argentina, and the United States, where its attributes under similar conditions are highly valued.

The Mpwapwa

The ***Mpwapwa*** breed (Fig. 4.33) was developed as a composite dual-purpose breed for milk and meat production in medium- and low-input production environments (Chawala et al. 2017). The breed was developed through a crossbreeding programme involving East African Zebu, Indian Zebu, and European dairy breeds, mainly Ayrshire. This crossbreeding programme was initiated in the 1920s.

The initial programme was halted in 1940, and a new programme was started in 1944, with the aim of creating an animal capable of producing 2300 kg of milk in a 305-day lactation, having a calving interval of 380 days, and steers attaining a 250-kg carcass weight at 4 years of age (Syrstad 1990; Bwire et al. 2005). To achieve this, additional genetics were introduced, including the Kenya Boran (*Bos indicus*), the Jersey, and Guernsey in addition to the Ayrshire as sources of European (*Bos taurus*) dairy genetics. The composite was declared a breed in 1958 (Kiwuwa and Kyomo 1970; Rushalaza et al. 1993), and a nucleus herd of Mpwapwa was established in 1958 to drive the breeding programme (Syrstad 1990). By the mid-1960s, at the Mpwapwa Livestock Breeding Station, the breed contained approximately 20% Tanganyika Zebu, 10% Boran, 5% Ankole, 55% Red Sindhi and Sahiwal, and 10% Ayrshire (Syrstad 1990). The

breed development continued, and in 1971, the breed composition was estimated to be 32% Red Sindhi, 30% Sahiwal, 19% Tanganyika Zebu, 10% Boran, and 9% Ayrshire and Shorthorn. Then the breed was selected towards Sahiwal, and by 1988, the Sahiwal content had reached 75% (Katyega 1987).

Unfortunately, the breeding programme has not been consistent throughout this period, and genotype stability (fixed genotype composition) has not been achieved. This phase was further complicated by factors such as disease outbreaks, droughts, inadequate nutrition, and a lack of enabling political and economic environments, all worsened by technical staff who were inadequate in driving the programme. For example, in the 1990s, the Mpwapwa cattle population declined significantly because of mortalities caused by East Coast fever (ECF), which led to the near extinction of the breed (Bwire et al. 2005). Consequently, breeding targets were not achieved, and new genetic lines, especially Sahiwal (*B. indicus*) from Kenya, were introduced.

There has never been more than 1000 pure Mpwapwa cows at any one time, and there has been little dissemination outside the original station (Wilson 2021). The Food and Agriculture Organization (FAO) of the United Nations has classified the Mpwapwa breed as being at risk of extinction (Syrstad 1990; Rege 1999), even before it has really been fully established. However, multiplication efforts from 1999 onwards supposedly increased the population of the breed owing to farmers' increased demand for improved cows and bulls for draught power. The efforts involved the multiplication of the pure Mpwapwa breed and the intensification of the increase in the number of these animals by back-crossing the available pure Mpwapwa with Boran and Sahiwal. The underlying consideration and assumption driving the breed choices and mating plans were that the Mpwapwa breed production potential was on par with Sahiwal, while the Boran cows were known to be better milkers than the Tanzania Shorthorn Zebu (TSZ) (Bwire et al. 2005).

However, a major challenge has been how to scale up a breeding programme to cover the needs of a wider breeder and consumer community—generating a large number of animals and systematically distributing these to farmers (Chawala et al. 2017). The target of 2300 kg of milk per 305-day lactation has not been realized, while the goal of 230 kg carcass per steer at the age of 4 years was realized in 1985. On-farm breed performance studies in the 1970s–1980s showed that the Mpwapwa cows were yielding four times more milk and had higher growth rates than the TSZ cows (Rushalaza et al. 1993), and the breed has been widely accepted by the community owing to its milk and meat yield, disease tolerance/resistance, and the ability of the bulls to be used for draught power (Komwihangilo et al. 2009).

There has not been a recent population census or estimate. By 1997, the estimate was 1000–1500 heads, and other than the animals on government stations, there were no 'purebreds' left on farms (Rege 1999). The Mpwapwa is clearly an example of a composite breed with a potential for high productivity and is liked by farmers. The failure for the breed to emerge as a major breed being used widely in Tanzania and neighbouring countries is principally an institutional failure to put in place a functional breeding programme to stabilize the breed and scale its use. If no steps are taken to address these, the Mpwapwa will disappear.

The Renitelo Breed

The Renitelo breed (Fig. 4.34) is a three-way composite beef cattle breed created at the Kianjasoa station (in Madagascar) by crossing Malagasy Zebu (25%) × Limousine (50%) × Afrikander (25%). The development of this breed was initiated in 1951, building on related cross-breeding work, which started in 1946, with the objective to produce a beef cattle breed suited for the typical Madagascar conditions. Although the breed was recognized in 1965, it was not registered. In 1992, the government took steps to revitalize the work on the breed. Interest in the breed had waned in the preceding period. Despite its

Fig. 4.34 A herd of Renitelo cattle of Madagascar. (Courtesy: Dr. Maria da Gloria Taela)

many valuable traits (e.g. its adaptation to a wide range of conditions in Madagascar, high growth rate, and draught power), the breed suffers from high sensitivity to the skin disease dermatophilosis (previously called streptothrichosis). The breed is currently at high risk of extinction.

The Mangan'i Boina Breed

The *Mangan'i Boina* (also known as *Manjan'i Boina*) is found in the Mahajanga province of Madagascar. It is a dairy type of breed created for the hot coastal climate of the Mahajanga province. It is considered to consist of (unknown proportions) the local Madagascar Zebu and the imported dual-purpose (dairy/beef)-type *Brune des Alpes* from France. Breed development was started in the 1980s, and it is still under formation. There were only 200 animals in 1998. The breed has not been registered, and without any concerted focus on its development, it will likely disappear.

The Wakwa Breed

The *Wakwa* breed (Fig. 4.35) is a composite cattle breed developed from crossing the American Brahman as the paternal line and the local Gudali of Cameroon as the dam line. The resulting F1 generation, although considered then to be susceptible to streptothricosis, proved to be most adaptable to the Cameroon environment. Through subsequent generations of inter se mating, the cross (named *Wakwa*) turned out to be tolerant of streptothricosis and was found to be a suitable beef animal for the local environment.

The Drakensberger

Although there is literature that refers to the Drakensberger of South Africa (Fig. 4.36) as a composite breed, it has a long history, which does not compare to the more recent composite breeds in this section. It dates back to the indigenous cattle possessed by the Khoi and Bantu tribes of the Western Cape of South Africa in the seventeenth century. Jan van Riebeeck supposedly crossbred the indigenous black cattle in 1665 with eight imported Gröningen bulls, which became known as 'Vaderlanders' in the early 1700s. Thus, the Drakensberger, also known as the Uys cattle (after the Uys family that played a significant role in the early days of the breeding), is considered to be the world's first synthetic or composite cattle breed, although there is no data on the proportionate genetic content of different cattle breeds from which it originated.

4.5 Well-Established Exotic Breeds in Africa

Although livestock have been part of the culture in SSA for a long time, the commercialization of animals based on specific traits is relatively new—a twentieth-century phenomenon. For a long time, individual herds of cattle were all that counted. The oldest archaeological evidence of domestic cattle dates back to between 6000 and 5000 BC. The Kushite Empire (300 BC–350 AD) used cattle for draught power to drive irrigation. However, the first recorded use of cattle in trading is reported in 1250–1450 AD in Great Zimbabwe, where cattle were traded together with ivory, gold, and salt. Further, cattle are documented to have been traded in the Zulu nation (1816–1897 AD). Recorded literature indicates that milk was a free commodity, representing good hospitality and community sharing. The indigenous breeds, which, by today's definition, are not dairy cattle breeds catered to these needs. With the exception of a few countries, the main dairy products consumed were liquid milk, sour milk, and butter.

Following the establishment of the first herd books in the late 1700s, most European cattle populations have developed into clearly defined breed types, and the selection for specific traits (e.g. with a focus on dairy, beef, or dual purpose) has been accompanied by an increase in the uniformity of colour and other external characteristics within each breed (Cunningham and Syrstad 2005). This specialization of breeds has, among other things, led to a significant reduction in the number of breeds in Europe and North America.

For example, today, more than half of the dairy cows in Europe and North America are of one breed type, the Holstein-Friesian.

The main driver for the utilization of popular and well-established exotic breeds in Africa has been the commercialization of livestock products stimulated by the post-Second World War globalization and driven by European settler farmers in the period before and following the political independence of African states. Subsequently, as the demand for animal products (meat, milk, and other dairy products) increased, so did the need for high-producing breeds. This has led to the importation of European cattle breeds, which, initially, were meant for the so-called high management farms and ranches. This trend has substantially increased post-independence, supported by international development agencies, and is increasingly driven by international private livestock breeding companies. In some countries, the intentional importation of tropical dairy (or dual-purpose) breeds such as Sahiwal or Brahman was done to serve the needs of poorly managed or 'low-to-medium-input' (smallholder) farms. This restriction policy for the European dairy breeds had some negative consequences for livestock development. For example, the introduction of Sahiwal from India and Pakistan during the colonial era essentially replaced efforts for the within-breed genetic improvement of indigenous breeds for smallholders in the highlands of Kenya. On the other hand, the unintended consequence of lifting the restriction policy for the European dairy breeds for the smallholder farms was the rapid introduction of the 'not-fit-for-purpose' European dairy breeds into poorly managed farms.

Exotic dairy breeds that are dominant in Africa today include Friesian, Jersey, Ayrshire, Holstein-Friesian, and Brown Swiss. Also widespread are Guernsey, Simmental/Fleckvieh, Red Dane, Dairy Shorthorn, and Normande, among others. Today, the dominant exotic beef breeds in Africa include Angus, Hereford, Charolais, Limousin, Brahman, and Gelbvieh.

Of the three main strategies for using exotic germplasm—breed replacement, continuous crossbreeding systems (e.g. rotational or criss-cross crossbreeding), and the creation of synthetic or composite breeds—the one widely witnessed across the continent is breed replacement, in which some farmers, usually large- and medium-scale, remove or reduce indigenous breeds on their farms to focus on one or more specific pure exotic breeds as a basis of their farming enterprise. As alluded to above, Africa has had a few initiatives aimed at developing composite breeds, but these have not been consistently successful. With regard to crossbreeding, while the practice is widespread, it is opportunistic and haphazard. Consequently, the continent has a 'fruit salad' of crosses of all kinds. For example, in eastern Africa, where the Holstein-Friesian has been widely used, there is a wide range of Friesian genes across and within smallholder farms. This would not be a problem if genetic composition was consistently a choice by farmers. Unfortunately, it is more a reflection of the absence of programmes to systematically develop appropriate breed combinations to supply farmers with the genetics they need. Where crossbreeding programmes have been tried, and there have been many across SSA, they have been short-term donor-funded research or development 'projects', and they have generally failed to consider the needs of farmers, which include production traits (e.g. milk, meat, and traction), adaptive attributes, and other more nuanced considerations such as product taste, animal colour, etc.

Overall, crossbreeding with exotic dairy cattle in Africa has been more widespread and has taken root in agro-ecological zones, which are similar to the temperate origins of these breeds. This can be seen in eastern Africa (the highlands of Kenya, Ethiopia, Uganda, and Tanzania) and South Africa.

The Holstein-Friesian (a combination of the original European Friesian, the North American Holstein, and intermediates between the two) dominates the global dairy industry and is also the leading exotic dairy breed in terms of numbers in pure and crossbred forms across the African continent. Most countries, which have considered specialized dairy animals, have almost invariably tried this breed, with varying

levels of success. Lessons learnt, especially in relation to its large body size and a lack of adaptability to the myriad production environmental and production system challenges—the inadequacy and low quality of feeds, heat, disease, etc.—have, in many countries, informed the introduction of smaller, 'less fragile' breeds such as the Jersey. Indeed, the Jersey is probably the second most widespread exotic cattle breed on the continent presently—with an estimated 34 African countries reported to have imported the Jersey at some point in the recent past or are actively doing so at the present time (Opoola et al. 2022).

Crossbreeding for milk and beef production in Africa using some of the major exotic breeds has been a subject of various studies (e.g. Wilson (2018), Cunningham and Syrstad (2005), Gregory et al. (1984), Wilson (2009), and Moyo et al. (1994)).

Table 4.6 presents a summary of some of the main exotic cattle breeds in Africa.

Although some of the exotic breeds are being used as pure breeds in Africa, all exotic breeds that have been introduced into Africa have been used in some form of crossbreeding with indigenous breeds. Indeed, their use in crossbreeding is more widespread than their use as pure breeds.

While some of the exotic breeds have been successfully utilized, there are significant yield gaps, that is, gaps between what is possible given the genetic composition of the animals and what is realized. This is particularly evident in the dairy sector. Some of the reasons for these gaps include a mismatch between the exotic genetics and the local smallholder production systems. Partly, this has been due to the fact that breeding goals and long-term breeding strategies for smallholder farmers have not been defined clearly. Although indigenous livestock breeds may not have levels of production (milk yield, growth rate, number of eggs, etc.) as high as their exotic counterparts under certain production systems, the indigenous breeds possess valuable traits such as tolerance and resistance to disease, high fertility, good maternal ability, unique product qualities, longevity, and adaptation to harsh environments and poor-quality feeds, which have not been appropriately exploited in the breeding programmes aimed at improving productivity. Overall, the use of exotic breeds in Africa has been consistently successful only under high levels of management in medium-to-large farms. However, in eastern Africa, especially Kenya, the successful use of exotic crossbreeds in smallholder dairy systems is a demonstration that smallholders can utilize these breeds when conditions, both production and market, are right.

4.6 Summary and Conclusion

Of the four main categories of indigenous African cattle—the humpless (*Bos taurus* or Taurine) cattle (discussed in Chap. 3), the humped (*Bos indicus* or the Zebu), the Sanga (Taurine × Zebu) hybrids, and the Zenga (Sanga × Zebu hybrids)—the majority of cattle breeds and strains on the continent are Zebu.

The Zebu and its derivatives (Sanga and Zenga types) are well-adapted to hot and dry environmental conditions and are known to be more resistant to tick infestations compared to Bos taurus cattle—both indigenous to Africa and exotic. Consequently, the Zebu are widely distributed in Africa, inhabiting the production systems in the expansive arid and semi-arid areas across the continent. They generally have larger body sizes and higher overall productivity levels in tsetse-free areas of the continent.

The population of the Zebu is highest in the East and the Horn of Africa region—in both highlands and lowlands, including the large arid and semi-arid land masses—compared to other regions. This distribution is, in large part, a legacy of the history of cattle introduction (the Zebu having entered the continent primarily through the Horn of Africa) as well as human migration patterns on the African continent. The two waves of cattle introduction into the continent and their subsequent migration led to a dominance of the Zebu-type cattle in Eastern Africa and explain the relative absence of distinct Taurine cattle in the sub-region. Indeed, there is only one remaining Taurine breed in the sub-region, the Sheko of

Table 4.6 Summary of exotic cattle breeds used in Africa

Exotic breed	Primarily imported from (country)	Country of established use (in Africa)	Focal trait(s)
Holstein-Friesian[a]	Denmark, the United Kingdom, the United States, New Zealand, Canada, Sweden, Australia	Burkina Faso, Burundi, Cameroon, Kenya, Côte d'Ivoire, DRC, Egypt, Ethiopia, Malawi, Nigeria, Rwanda, Senegal, South Africa, Sudan, Tanzania, The Gambia, Uganda, Zambia, Zimbabwe	Dairy
Jersey	The United Kingdom (Island of Jersey), New Zealand, the United States	Angola, Botswana, Burkina Faso, Burundi, Cameroon, Chad, Côte d'Ivoire, Democratic Republic of the Congo, Egypt, Eritrea, Eswatini, Ethiopia, The Gambia, Guinea, Ghana, Lesotho, Kenya, Liberia, Libya, Madagascar, Malawi, Mozambique, Namibia, Nigeria, Rwanda, Senegal, Seychelles, Somalia, South Africa, Sudan, Tanzania, Uganda, Zambia and Zimbabwe	Dairy
Ayrshire	The United Kingdom, Canada	Kenya, South Africa, Tanzania	Dairy
Guernsey	The United Kingdom (Island of Guernsey)	South Africa, Kenya	Dairy
Tarentaise	France	Burkina Faso, Egypt, Algeria, Morocco, Tunisia, Zimbabwe	Dual purpose (Dairy and beef)
Montbéliarde	France	Niger, Burkina Faso, Cameroon, Côte d'Ivoire, Senegal, Sudan, The Gambia, Morocco, Zimbabwe	Beef
Charolais	France	Botswana, Kenya, Namibia, Rwanda, South Africa, Zambia, Zimbabwe	Beef
Brown Swiss	The United States	Nigeria, Kenya, South Africa	Dual purpose (Dairy, beef)
Simmental	Switzerland	Cameroon, Kenya, Namibia, Nigeria, South Africa, Zambia, Zimbabwe	Dual purpose (Dairy and beef, and also draught power)
Danish Red	Denmark	Tanzania, Zimbabwe	Dairy
Fleckvieh	Austria, Germany	Kenya, Namibia, South Africa	Dual purpose (Dairy, beef)
Gelbvieh	Germany	South Africa	Dual purpose (Dairy, beef)
Pie Rouge des Plaines	France	Tunisia	Dairy
Hereford	Originally, the United Kingdom (Herefordshire in England); more recent imports come from secondary sources (e.g. the United States, Canada, and Australia)	Kenya, South Africa, Zambia, and Zimbabwe	Beef
Angus	Scotland (original home) and secondary sources the United States, Canada, Argentina, New Zealand, and Australia	Angus: Kenya, Namibia, South Africa, and Botswana Brangus (the United States and Canada): Developed from Brahman and Angus and notable for its resistance to heat; is present in South Africa and a few other African countries, including Namibia and Kenya	Beef

Box 4.1 Summary of the risk status of cattle breeds in Africa

Africa is home to a total of 145 cattle breeds/strains comprising two Taurine Longhorns, 15 Taurine Shorthorns, 75 Zebu (*Bos indicus*), 30 Sanga, eight Zenga (Zebu–Sanga), nine breeds that are derived from the interbreeding of indigenous breeds/strains located in close proximity to each other, and six systematically created composite breeds. Out of the 145 breeds identified from the survey, 47 (about 32%) were considered to be at risk of extinction. The risk categories used were: Critical (most severe), Endangered, Vulnerable, and Rare (least severe). Of the breeds identified to be at risk of extinction, six were in the Rare category, ten were Vulnerable, another ten were Endangered, and 15 were in the Critical category. A total of 22 breeds (about 13%) previously recognized on the continent have become extinct in the past century. This number excludes some populations, which have lost their individual identity due to admixtures involving two or more originally distinct breeds.

Source: Rege (1999).

South-west Ethiopia and the eastern parts of South Sudan. Box 4.1 is a summary of the findings by Rege (1999) with regard to the risk status of cattle breeds in Africa. The situation has changed significantly, and many more breeds are at escalated risk levels than they were back in 1999. An updated comprehensive survey is overdue.

Although across the continent, the population of the Zebu as a group remains large and the overall genetic diversity high, there are threats, increasingly placing several specific strains or breeds (of Zebu and its stabilized derivatives) at risk of extinction, with some already extinct and others facing extinction. Crossbreeding presents the highest risk. As a result, several existing Zebu breeds and their derivatives are critically endangered, having fewer than 1000 animals. Four of these are Small East African Zebu (Mkalama Dun, Pare, Chagga, and Baria), and three are South African Sanga (Nkone, Pedi, and Shangan).

Many early African societies, especially nomadic groups, depended almost entirely on livestock, with cattle playing a central role. Pastoralism remains an important system on the continent today, as exemplified by the Fulani, Maasai, and the Tuareg communities. Across the continent, cattle remain major sociocultural assets, playing important economic and sociocultural roles, as well as major sources of animal protein (milk and meat), draft power, and manure that contribute to crop agriculture.

African indigenous breeds are considered to be poor performers relative to exotic breeds in terms of outputs of products (e.g. meat or milk) per animal and unit of time. While this is true on the surface, it does not consider the adaptive attributes of the indigenous breeds and the fact that the more 'productive' exotic breeds can hardly survive in the (most dominant) production environments in which the indigenous breeds are able to not only survive but also produce and support the livelihoods of their owners. Moreover, while commercial exotic cattle breeds, provided with enabling production environments, excel because they have been continuously selected for the spe-

cific productivity traits, some indigenous African breeds are known to inherently have either good dairy or beef potential or both. But only limited effort has been made to fully exploit these potentials. Outstanding examples of Zebu cattle and their derivatives covered in this chapter include the dual-purpose group (exhibiting good dairy and beef production attributes), comprising the White Fulani cattle (West African Zebu) and Fogera cattle (Zenga); the dairy types, including the Kenana and Butana cattle of Sudan, which are among the best milk-producing Zebu breeds globally; and the beef types, which are exemplified by the Boran or Borana, which are now globally recognized and sought after. The potential for within-breed improvement among indigenous African breeds is, indeed, huge.

Moreover, while intensive and consistent artificial selection and management interventions have resulted in marked productivity improvements among cattle (and livestock, more broadly) in the global North, this has come at a cost: reduced genetic diversity. The immediate consequence is expressed in such performance traits as fertility, which suffers significantly in inbred animals (an extreme case of lack of diversity). The long-term consequence is more dire: loss of options for addressing yet unknown production challenges and/or human requirements of the future. In contrast, most African cattle breeds have not been selected consistently for productivity gains. The main (natural and artificial) selection focus has been on survival in the largely unpredictable, harsh, and changing environmental conditions. The major threat African breeds have faced has been genetic dilution, historically, through interbreeding among neighbouring breeds, and more recently, through haphazardly and inconsistently executed, widespread crossbreeding. Although artificial selection programmes have been tried, these have tended to be short-term 'projects', and there are only limited cases of sustained efforts on within-breed genetic improvements.

The narrative that indigenous African breeds have inherently low productivity has led to the shift in attention to genetic 'upgrading' with and replacement by exotic breeds from the global North. Today, the continent has, in addition to the four main indigenous cattle categories, a fifth as well as a sixth category. The fifth category consists of the composite breeds developed through systematic crossbreeding involving one or more indigenous breeds with one or more imported commercial breeds. Crossbreeding and the formation of composite breeds is intended to create fit-for-purpose breeds for specific production contexts. The sixth category includes the pure exotic breeds that are directly imported, maintained, and used for commercial production. Some of the exotic breeds are thriving in specific locations of the continent under commercial production systems for dairy, beef, or dual purpose. On the other hand, efforts to create composite breeds have faltered, in major part because they were driven by the public sector—government research—efforts to create genotypes that should (at least from technical considerations) provide a desirable combination of adaptation and productivity traits. Unless the private sector is involved in the design and implementation of these breeding programmes and the needs and capabilities of smallholders are considered, such programmes will continue to be restricted in existence only on research stations and government ranches.

5 African Goat Genetic Resources, Diversity and Unique Features

Moses Okpeku, Martha N. Bemji, Isidore Houaga, Khaled Fantazi, Liveness J. Banda, Timothy Gondwe, Sebastine Chenyambuga, Sahar A. Elnahta, Doctor M. N. Mthiyane, Shumuye Belay, Tadelle Dessie, Taiye S. Adewumi, and Oliver Hanotte

Abstract

This chapter introduces indigenous African goats, exploring their origins of domestication, dispersal and distribution across the African continent. The first two sections provide a general overview (Sects. 5.1 and 5.2). The following three sections (Sects. 5.3, 5.4, and 5.5) are devoted to the history of domestication, dispersal and distribution, tracing the journey from the centres of domestication to

their present-day locations. Section 5.5 focuses on the characterisation of available genetic diversity, categorising goats into three major groups: indigenous, exotic and composite breeds. Each subsection examines the origin, distribution, classification, physical characteristics, adaptive characteristics and production characteristics of named breeds. Section 5.6 discusses the characterisation of genetic diversity in African goats. It highlights the role of modern molecular markers in the characterisation of genetic diversity and the utilisation of known gene regions to understand adaptation, physiology and production functions in goats. Section 5.7 presents an overview of indigenous knowledge on the utilisation of various goat products. The chapter concludes with a future outlook (Sect. 5.8) on African goat genetic resources, utilisation and potential conservation strategies for the present and future.

Keywords

Africa · goat · genetic resources · diversity · characterisation

5.1 Introduction

Africa is home to the largest animal diversity on earth, with sub-Saharan Africa accounting for the majority of this diversity (UNEP-WCMC, IUCN 2016; Chapman et al. 2022). Goats are a ubiquitous animal genetic resource found across the globe (Stella et al. 2018), and Africa is the second largest home to goats in the world, accounting for 36.4% of live animals, with total goat meat and milk production estimated at 1,082,120.07 tonnes (23.4%) and 3,674,644.96 tonnes (23.1%), respectively (FAOSTAT 2019). Nigeria, Sudan, Chad and Kenya are key producers of goats on the continent, bringing them into the rank of ten top producers in the world (FAOSTAT 2019).

African goats are referred to as 'the poor man's cow' (Steele 2006) because of their important roles in rural agricultural systems. They feature conspicuously in the economy of most nations of the world, particularly in the rural poor agricultural systems where they are kept for food and their roles in the sociocultural and financial security of their keepers (FARM-Africa 1994). Their small stature has many advantages, which include easy acquisition, rearing and maintenance, cheaper to raise than cows with nearly the same economic return, and exploitation of marginal lands.

A total of 289 goat breeds/populations exist in Africa (AU-IBAR 2019), the majority of which are not characterised. Eastern Africa has the highest number of goat breeds (101), followed by Southern Africa (79), Western Africa (47), Northern Africa (33) and the Central African region (29). The highest number of goat breeds is found in Ethiopia (26), followed by Tanzania (17), Sudan (12) and Kenya (10). Cameroon and Chad have seven and eight goat breeds, respectively. Nigeria and Mali have the highest number, at nine breeds each in West Africa, while the number of breeds ranged from seven to nine in North Africa, comprising Egypt (9), Algeria (8), Mauritania (8) and Morocco (7).

African goats have a long and intertwining history with their human keepers' culture and traditions: featuring in tales and stories, used for religious worship, marriage contracting and dowry payment, and much more. Apart from these, goats are kept majorly for the meat, a savoured delicacy, relished in many African communities that goes well with many traditional dishes and has no taboo attached (Oluwatayo and Oluwatayo 2012). Almost all parts of the goat are useful. Major economic values come from the meat (protein), hide is used for quality leather works, the horns, hooves and bones are also sourced after for art and craft materials. Their fur finds great use in the fabric industry, while faecal droppings and intestinal contents are regarded as a valuable source of manure exploited by the rural poor farmers as a source of cheap fertiliser for use on farmlands.

Goats found with local residents are referred to as **indigenous goat types**; these are particularly adapted to the regions where they are found and have a history as old as the local inhabitants. Non-resident goat types imported from elsewhere within the continent or from outside the continent into a region are regarded as **exotic goat types;**

these are often imported to cross the indigenous type (for varied reasons), and the hybridised generation is referred to as **locally developed goat types** (Dekkiche 1987; Takoucht 1998).

Indigenous African goats represent a strategic genetic resource with unique features and diversity (Monua et al. 2020; Magoro et al. 2022). Their unique features include: **Adaptability**; the ability to thrive and survive on marginalised resources (Daramola and Adeloye 2009). This includes the evolution to thrive in a range of environments, from arid and semi-arid to regions of extreme humidity (Monua et al. 2020). This also includes the evolution of a digestive system that enables them to extract the maximum amount of nutrients from their food and disease tolerance, which enhances their survivability in harsh and hostile environments in Africa (Daramola and Adeloye 2009; Berihulay et al. 2019; Akinmoladun et al. 2020). In terms of **genetic diversity**, there are many different breeds of indigenous African goats, each with its own unique characteristics. The evolution of a diversity of coat types and colours and varied morphological characteristics, which make them fit well into the specific locations where they are found and the culture and traditions of their owner make them remarkable (Berihulay et al. 2019) specimens. Different breeds of goats are subsequently discussed, taking into consideration the following: *origin and distribution*, p*hysical characteristics, adaptive and special genetic characteristics* and t*ypical production systems and production characteristics.* See Chap. 2 for comprehensive information on production systems of some named breeds to reflect their geography, adaptation and uses where they are found. The named goat breeds discussed are listed in Table 5.2.

5.2 Origin and Domestication of African Goats

Animal genetic resources represent actual genetic material and/or their potential value. Goats are small ruminants belonging to the tribe called *Caprini,* which is further divided into two genera, *Capra* and *Hemitragus*. The domesticated goat originates from the *Capra* genus with 60 chromosomes and includes five species (Table 5.1), as reported by Steele (2006).

The development of the domestic goats of the world has long been a subject of serious debate. It was general knowledge that the domesticated goats of the world were derived from the ancient wild species, but there was no strong evidence of the true ancestor of the domesticated goat among the known wild goat types: *Capra aegagrus, Capra ibex, Capra Caucasica, Capra pyrenaica*, and *Capra falconeri* (Table 5.1). However, recent research suggests the Bezoar (*Capra aegagrus*), native to the montane forests of the Caucasus and the Zagros Mountains and also found in Eastern Europe, the Middle East and Asia (Eckart 2024) is the most likely ancestor of domestic goats—*Capra hircus* (Lin et al. 2013). A DNA study by Colli et al. (2015) places Bezoar goats (*Capra aegagrus*) as the wild ancestor of domestic goats, with multiple domestication centres contributing to the existence of the domesticated goats (Daly et al. 2018). The author and the team emphasise the need for ancient genomics to shed more light on the pattern of domestication, which is mosaic. They suggested that although this domestication took place in different places, with different people, the same wild goat (Bezoar goat) was linked to the domestication of African goats. Another study by Daly et al. (2018) pointed out the weak phylogenetic relationships between the other four wild goats with *Capra hircus,* discarding their contribution to the domestic goat development.

A signature of population expansion in bezoars of the C haplogroup suggested an early domestication centre on the Central Iranian Plateau (Yazd and Kerman Provinces) and in the Southern Zagros (Fars Province), possibly corresponding to the management of wild flocks. However, the contribution of this centre to the domestication of the goat population of this era is rather low (1.4%). A second domestication centre covering a large area in Eastern Anatolia, and possibly in Northern and Central Zagros, was proposed (Naderi et al. 2008). This last domestication centre (around modern-day Iran) (Alberto et al. 2018) is taken as the likely origin of almost all domestic goats today; this is consistent with

Table 5.1 Five sub-species of *Capra* (domesticated goat)

S/N	Species of goat	Centre of origin
1	*Capra hircus* (Bezoar)	West Asia
2	*Capra ibex* (Ibex)	Central Asia, Near East, Alps
3	*Capra Caucassica* (Tur)	West Caucasia
4	*Capra pyrenaica* (Spanish Ibex)	Pyrenees
5	*Capra falconeri* (Markhor)	Afghanistan/Pakistan

archaeological data identifying Eastern Anatolia as an important domestication centre (Daly et al. 2018; Naderi et al. 2008; Alberto et al. 2018; Naderi et al. 2007; Zheng et al. 2020; Daly et al. 2021). Goat domestication was probably achieved in present-day Iran and Iraq by 10,000 BC, from where goats entered into North Africa around 7000–6000 BC (Mason 1984; Shackleton 1997; Zeder 2008) and dispersed southward until they reached the coastal regions of the South.

True goats do not occur wild in Africa. African goats were introduced from the centre of domestication through Southeast Asia trade routes. Although the exact origin and path of arrival in Africa have been long debated, goats found in Africa are believed to have originated from the Zagros Mountains, from where they migrated as companion animals with the humans (Zheng et al. 2020; Joubert 1973).

5.3 Dispersal and Distribution of Goats Across Africa

The dispersal and distribution of goats across Africa from archaeological and genetic findings provide insights into their migration and genetic history, suggesting that goats entered Africa from the Middle East around 7000 years ago, accompanying human migration (Zheng et al. 2020). Genetic studies also identified multiple waves of migration and mixing with North African goats as humans migrated, shedding light on the complex dispersal patterns of goats across the continent (Zheng et al. 2020; Chynoweth et al. 2015; Pereira et al. 2009; Amills et al. 2017; Cooper 2021). Following domestication, goat dispersal followed human movement and trade routes as companions (Pereira et al. 2009; Amills et al. 2017).

They were originally kept for food and carried along because of the ease of transportation and their quick adaptation. The preference for goat meat and milk by human beings as food helped in the fast dispersion across Africa and the rapid spread to Central Sahara and the Ethiopian highland between 6500 and 5000 years ago (Amills et al. 2017; Cooper 2021). The quick dispersal and distribution of goats across Africa was aided by their ability to adapt quickly and survive on meagre feed, where other larger ruminants failed. Their dispersal across Central Africa might have been slowed down by trypanosomiasis, transmitted by tsetse fly (Amills et al. 2017). However, the population that survived are believed to have continued to travel with their human companions and finally reached the southern parts of Africa about 2000 years before the present time. Today, goats are found everywhere, from the high-temperature, arid northern region to the marshy swamps and salty coastal region in the south of the continent (Zheng et al. 2020; Amills et al. 2017).

5.4 African Goat Genetic Resources

Across Africa, from the arid north to the ocean bank in the south, across plains, grassland and safaris, even mountains, dense forests and marsh swamps on the continent have some form of goat inhabiting them. The African goat genetics resources represent a great diversity described differently **by size** into small, medium and large types; **by production** into dairy and meat types; by hair length as long and short hair types; by location into Northern, Western, Central, Eastern and Southern types. On the account of historical origin, they have been broadly grouped into

indigenous, **exotic** and **developed** breed types. Among the indigenous class, five breed groups have been recognised, which include (i) Lop-eared, (ii) Short-Eared Small-Horned and (iii) Short-Eared Twisted-horned. This complex diversity has also been described phenotypically using known morphology, but physical resemblance is limited, so molecular characterisation has also been explored in these goats to understand their genetic architecture for immediate and future use and conservation. This chapter summarises the different modes of classification of these complex diversities (Sect. 5.6) and presents some important value chains derived from the African goats.

5.5 Characterisation of Genetic Diversity in African Goats

The characterisation of animal genetic resources provides valuable information for classification, use and prioritisation for conservation. Such information includes phenotype, genotype and history of use and distribution. Genetic and historical information curated on the goat varies from place to place in Africa and is dependent on countries, national priorities and goals for animal genetic resources. In order to synchronise the different characterisations used in literature, we have arranged the different groups by origin into indigenous, exotic and developed types and, under these, described some common types by phenotype, production and physiology. Later in the chapter, we considered molecular characterisation and indigenous knowledge on some value chain products.

Research indicates that goats did not enter sub-Saharan Africa until about 4000 years ago, with genetic markers suggesting that the dispersal of goats into North Africa may have been the result of maritime trading, with male goats being introduced from Southwest Asia along the North African coast (Chynoweth et al. 2015).

The article 'A Brief History of Goat Domestication' by Tamsin Cooper emphasises the social nature and adaptability of goats, which enabled their domestication and subsequent spread across different regions. It highlights the importance of protecting local and heritage goat breeds to maintain the diversity of the worldwide gene pool, crucial for the survival of goats in a changing future (Cooper 2021).

In summary, the dispersal and distribution of goats across Africa have been influenced by human migration and trade, as evidenced by archaeological and genetic studies. The genetic history of goats provides valuable insights into their complex migration patterns and the need to preserve genetic diversity for the sustainability of goat populations.

5.5.1 Indigenous Goat Breeds

Indigenous or local goats represent goat populations developed in a particular region over time and are adapted to the prevailing local environment. They are an active part of the culture and tradition of the people and locality where they are found. Across all regions of Africa, there are unique goat types associated with the people and their cultural history. These classes of goats can best be described by regions as northern, western, eastern, central and southern in origin. Some of these also bear regional names, like the West African dwarf goats found in the western, central and eastern regions of the continent. Their northern counterparts are sometimes referred to as northern or Arab goats. Within each region, the diversity exhibited by these goats has necessitated the use of unique breed names as well. The majority of the native goats are generally characterised by small stature, multicoloured coats, and hardiness, with unique adaptation features to regions where they are found. They can be very prolific, with twins and triplets being common among some breeds. They are particularly close to and found very useful applications in local, smallholder agriculture (Monua et al. 2020; Okpeku et al. 2011a; Tarekegn et al. 2019).

5.5.1.1 Lop-Eared Goats

This group of goats is characterised by the long drooping (lop) ears and includes the Zaraibi of Egypt and the **Nubian** of the Sudan. Similar

types of goats are heavily represented in the region of North Africa. The ancestral stock might have evolved either in India, subsequent to the Indus Valley civilisation or west of India, possibly Iran, from where it spread to Syria and Egypt in the west. It is also possible that this goat type evolved from the screw-horned goats common throughout the ancient world, from India in the east to Libya in the west, judging from the screw horns common in the different breeds found in different parts of Africa. The so-called Nubian goat probably does not in fact originate from Nubia (the area of southern Egypt and northern Sudan) and certainly not from Ethiopia, but bears the convex profile, a common characteristic of goats found in the Middle East and India (Mason 1984). It is therefore possible that the different breeds found in Africa are close relatives or descendants of those found in the Middle East and Asia. The lopped-ear goats share common features which have been extensively documented in the literature. However, there are a couple of unique features that separate breeds from region to region. It has been argued that these features were perhaps developed at a later stage after domestication in response and adaptation to the prevailing environments where they are found. This adaptation feature is perhaps the reason why goats are so ubiquitous and found everywhere.

5.5.1.2 Nubian Goats

Origin, Distribution and Classification: Nubian goats (Fig. 5.1) are said to have originated in Africa, especially in the Sudan region. However, they have long been popular in India and the Middle East as well. The Lop-eared Nubian goat, also known as the Anglo-Nubian goat, was developed in the nineteenth century as a result of extensive crossbreeding between imported Nubian goats and a variety of native British goats. They are found commonly in the Middle East, North Africa and more than sixty other countries (Porter et al. 2016). They are believed to have been brought from France, through the eastern Mediterranean to the regions between Egypt and Sudan along the Nile, referred to as Nubia (Britannica 2016), this is where the word 'Nubian' was first used. Despite their existence in several Asian, African and Central/South American nations, this species is widespread and not at risk. However, the lack of suitable, unrelated breeding partners puts available small, isolated groups in danger.

Fig. 5.1 Nubian goat

Physical Characteristics: The Nubian is frequently referred to as a royal animal with long, broad ears that droop, huge almond-shaped eyes, a prominent forehead, a convex 'roman' nose, a tall, flat-sided body, long legs and a short, shiny coat, all contributing to the Nubian's unique appearance. The goat's short coat might be spotted, parti-coloured, or any other solid colour, including golden brown, reddish-brown, black and dark grey, with the most common colour being a blend of brown and white (Porter et al. 2016). White facial stripes might be a sign of crossbreeding with Swiss-born goats. Bucks average 36 in. (90 cm), and does 32 in. (80 cm). Mature weights are usually a minimum of 174 lb. (79 kg) for both sexes and a maximum of 309 lb. (140 kg) and 243 lb. (110 kg) for bucks and does, respectively (Porter et al. 2016; Transboundary breed summary 2024).

Adaptive Characteristics: Nubians are able to adapt to hot temperatures due to their wide ears and flat flanks. They do not, however, fare well in humid environments. They have great fecundity and can reproduce all year long.

Production Characteristics: Compared to most other goat breeds, the Nubian has milk with a greater fat content. They produce 6.6 lb (3.9 kg) of milk on average every day, or 1920 lb (871 kg) over a period of 305 days, containing 4.8% butterfat and 3.5% protein. The majority of Nubians have genes that result in high levels of alpha s1-casein synthesis, a crucial protein for cheese-making and a significant goat milk advantage (Rahmatalla et al. 2022). They are also produced mainly for meat and milk (Kholif et al. 2020). Crossbreeding with native stock is very common in Latin American, Asian and African nations to increase milk or meat output. These are unique products of economic benefit derived from Nubian goats.

5.5.1.3 Sinai Goats

Origin and Distribution: Lop-eared Sinai goats are domestic goats that originated in the Sinai Peninsula, a triangular landmass located between the Mediterranean Sea and the Red Sea, and are found specifically in the southern part of the Sinai Peninsula, in Egypt (Pereira et al. 2009; Monteiro et al. 2021).

Physical Characteristics: Lop-eared Sinai goats are characterised by their drooping or lop ears, which is a distinct feature of the breed (Monteiro et al. 2021). The breed has a medium-sized body with a well-developed chest and a straight or slightly convex profile, with a short and dense coat that comes in various colours, including white, black, brown and a combination of these (Monteiro et al. 2021).

Adaptive and Special Genetic Characteristics: These goat types are adapted to the arid and harsh environment of the Sinai Peninsula, characterised by high temperatures, low rainfall and limited vegetation (Monteiro et al. 2021). They are known for their ability to browse on a wide range of plant species, including shrubs, trees and herbs, which allows them to survive their arid habitats. The breed is also known for its resistance to various diseases and parasites, a valuable trait in the challenging environment of the Sinai Peninsula (Monteiro et al. 2021; Nguluma et al. 2021; Kardjadj and Ben-Mahdi 2017).

Typical Production Systems and Production Characteristics: The production systems for the lop-eared Sinai goats are extensive, with the goats being raised in semi-nomadic or nomadic herds (Monteiro et al. 2021). They are raised mainly for the meat and milk, which contribute importantly to the local community diet, particularly cheese, which is highly valued in the region. They also contribute meat as protein (Monteiro et al. 2021).

5.5.1.4 Swazi/Nguni

Origin and Distribution: Lop-eared Swazi/Nguni goats are indigenous to South Africa, specifically the Swaziland and Nguni regions. They are part of the Indigenous Veld Goats (IVG) group, which includes pure-bred indigenous ecotypes represented by the IVG-Association (Visser and Snyman 2023).

Physical Characteristics: Lop-eared Swazi/Nguni goats are medium- to small-framed, well-proportioned, with strong, fine legs (FAOSTAT 2019). They have lop ears that hang down (Visser and Snyman 2023). They have a variety of coat colours, including black, white and multicoloured, and possess morphological variations between and within populations, leading to some categorisation based on quantitative data (Nguluma et al. 2021).

Adaptive and Special Genetic Characteristics: The breed is referred to as an untapped genetic resource (Visser and Snyman 2023) that is highly adapted to the South African region. Adaptation to harsh environments in this breed may be linked to the morphological appearance and/or physical attributes, including lop ears (Onasanya et al. 2021).

Typical Production Systems and Production Characteristics: Indigenous goat production in the southern Africa region is typically an extensive system with goats often allowed to scavenge for food and water.

5.5.1.5 Berber

Origin and Distribution: Lop-eared Berber goats are a breed of domestic goats that are native to the Amazigh communities of Morocco. These

goats were adopted by the Berbers for subsistence agriculture, and they have been an integral part of the local farming systems for many years (Hossaini-Hilaii and Benlamlih 1995).

Physical Characteristics: This goat type is known for its distinctive drooping ears, which hang on the side of its head. The breed has a compact and sturdy body with a deep chest and straight back with varied coat colours, including white, black, brown or a combination of these colours. Both males and females of this breed have horns, which are usually twisted and grow outward and backward (Benjelloun et al. 2011; Boujenane et al. 2016).

Adaptive and Special Genetic Characteristics: Lop-eared Berber goats are well adapted to the mountainous and arid regions of Morocco, where they are raised. These goats have excellent adaptability to difficult environments, which contributes to their success in various production systems. They are also among a few goat breeds that are well adapted to climbing trees (Benjelloun et al. 2015, 2016).

Typical Production Systems and Production Characteristics: Lop-eared Berber goats are primarily used for subsistence agriculture by the Amazigh communities in Morocco. They are raised for meat and milk production mainly and also for their hides and fibre. Their production systems are not well documented in the literature, but it is basically similar to the extensive production system common with most indigenous African goats. In addition, local farmers use them for bush control, as they are very effective in this role (Hobart 2022).

5.5.1.6 Benadir

Origin and Distribution: Lop-eared Benadir goats are a breed of goat that originated in Somalia. They are commonly found in the Benadir region of southern Somalia as well as in the neighbouring regions of Kenya and Ethiopia (Fereja 2016).

Physical Characteristics: Lop-eared Benadir goats are medium-sized goats, with males weighing between 45 and 55 kg and females between 30 and 40 kg (Fereja 2016). They have long legs and drooping ears that hang over their shoulders; their coat colour is typically black or brown, although some individuals may have white markings on their faces or legs (Fereja 2016).

Adaptive and Special Genetic Characteristics: There is limited information available on the adaptive genetic characteristics of this breed. However, as a breed that has evolved in a harsh, arid environment, it is likely that they possess traits that allow them to thrive in such conditions, such as drought tolerance and disease resistance.

Typical Production Systems and Production Characteristics: Lop-eared Benadir goats are primarily raised for meat production (Fereja 2016). They are well-suited for the arid, semi-arid and sub-humid regions of East Africa, where they are often kept in pastoral production systems characterised by extensive grazing on natural pastures, with little or no supplementary feeding (Fereja 2016). According to Nguluma et al. (2021), indigenous goat production in East Africa faces several challenges. The authors also reported morphological variations in the goat populations from this region, suggesting the possibility of selective breeding to improve productivity. Sufficient understanding of their genetics and production characteristics is important before embarking on improvement work.

5.5.1.7 Wahati

Origin and Distribution: Lop-eared Wahati are indigenous to Tanzania (Nguluma et al. 2021). They are found in different agroecological zones of Tanzania, including Pare, Gogo, Maasai, Tanga, Sukuma, Lindi, Ujiji, Pwani, Fipa, Songwe and Newala (Nguluma et al. 2021).

Physical Characteristics: Morphological variations between and within goat populations based on quantitative data have been reported for the breed (Nguluma et al. 2021). High twinning has also been observed in Ujiji and Lindi goats and low for Sukuma. The dominant coat colour is white in Pare, Gogo, Maasai and Tanga. Other coat colour patterns are mixed black and white for Sukuma and reddish-brown for Pwani and Maasai (Nguluma et al. 2021).

Adaptive and Special Genetic Characteristics: There is a paucity of information on adaptive and

special genetics for this population in the literature, suggesting the need for research into this.

Typical Production Systems and Production Characteristics: This goat breed is often raised in village goat production systems in Tanzania, where feed shortage, prevalence of diseases and water scarcity are the major goat production constraints (Nguluma et al. 2021). Common diseases in the breed population include contagious caprine pleuralpneumonia and helminthiasis (Nguluma et al. 2021).

5.5.1.8 Begait

Synonyms: Barka, Hassan, Bellenay and Beni-Amer

Origins, Distribution and Classification: Lop-eared Begait or Barka goats descended from the pasang (*Capra aegagrus*), which is probably native to Asia (Nigatu 1994). These goat breeds are grouped under the Nubian goat family (FARM-Africa 1996). They are among indigenous goat types and distributed in the northwestern lowlands of Ethiopia (west and northwest Tigray), Eritrea's Barka Valley and eastern Sudan. More than 110,000 Begait goat populations are estimated to be found in the northwestern and western zones of the Tigray region only. The goat producers in Ethiopia sometimes call it 'Barka' for the Begait goats because they have very similar phenotypic characteristics, though they have some unique features in each breed (eg in coat colour difference and neck length). The name 'Barka' is commonly used in Eritrea and Begait in Ethiopia. The breed is also named Bellanay and Beni-Amer because they are kept by these two ethnic groups in Eritrea. All in all, this breed is grouped under the Nubian family and distributed in three African countries.

Physical Characteristics: Body size, horn shape, ear shape and coat types are key physical characteristics used in classifying Ethiopian goat families and breeds (Gizaw et al. 2010). Begait goats are a dual-purpose goat population mainly used for milk and meat production. They have a large body size, horns with backwards orientation, heavy and drooping ears, a concave face profile, white (43%) and white with black (31%) coat colours, fast growth, a large udder and teat, and have no wattles. Under an extensive production system, the mean body weight of a mature buck is 45 kg and 38 kg for does; height: male 74 cm and female 68 cm (Berihulay et al. 2019).

Adaptive and Special Genetic Characteristics: Adaptive features in this meat goat breed include environmental and production adaptability, reproductive and growth rates, and carcass (Luginbuhl et al. 1998) and milk characteristics. It is adaptable to arid and semi-arid environments. The SCN9A and CAB39L candidate genes are identified in Begait goats, which are associated with body size and weight, and cell adhesion receptors, and growth factor receptors, respectively (Berihulay et al. 2019).

Typical Production Systems, Husbandry Practices and Production Characteristics Goat production systems in Ethiopia vary depending on the region and the breed of goat. Almost all goat production systems in Ethiopia have been classified as traditional, with the majority of goats being raised under extensive management systems (Fereja 2016). Natural pasture, browse species, crop residue and crop aftermath are the main feed resources for Begait goats. Communal grazing is the most abundant feed source for these goats, but grazing drastically reduces in the dry season. They do not have a permanent shelter because they migrate from place to place in search of food and water, especially during the dry season. However, farmers in urban areas used permanent houses. Goats and sheep are managed or housed together. Average weight at birth, 3, 6, 9 and 12 months is 2.8 ± 0.04, 11.1 ± 0.43, 16.5 ± 0.49, 19.6 ± 0.37 and 24.1 ± 0.48 kg, respectively, in the semi-intensive production system and 2.6 ± 0.03, 10.3 ± 0.46, 14.8 ± 0.57, 17.1 ± 0.49 and 20.6 ± 0.54 kg in the extensive production system. Litter size of the Begait goat varies from 1 to 3, with the mean of 1.53 ± 0.03 in semi-intensive and 1.51 ± 0.03 in extensive production systems. Begait does (Fig. 5.2a) supplemented with vetch hay provide 48 kg of milk within 71 days of lactation length (Berhane and

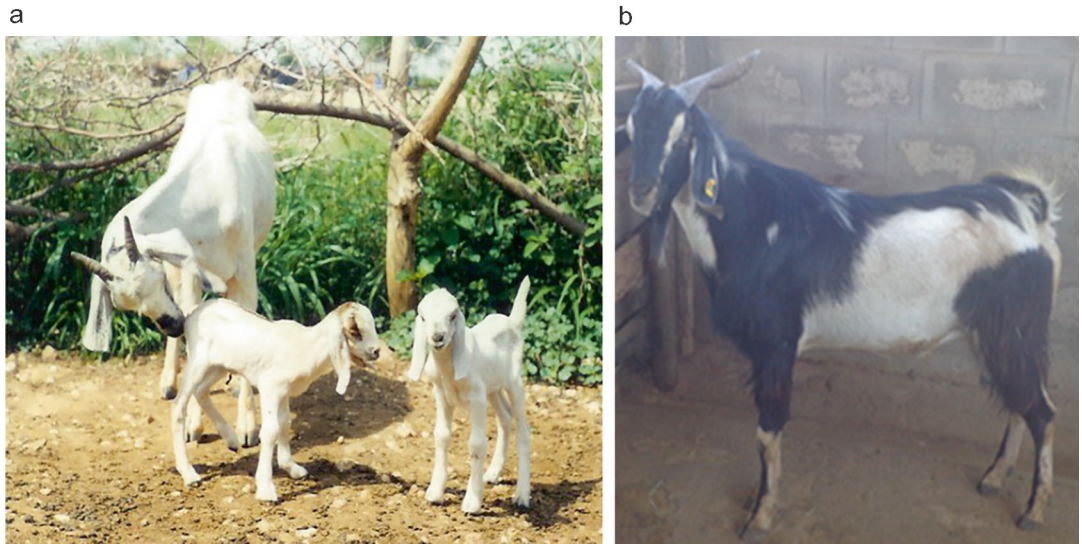

Fig. 5.2 (**a**) Begait does with its kids. (Photo by Shumuye Belay). (**b**) Begait buck. (Photo by Shumuye Belay)

Eik 2006), bucks (Fig. 5.2b) are also maintained on supplements in harsh weather.

5.5.1.9 Baladi

Origin and Distribution: Lop-eared Baladi goats are indigenous goats found mainly in the Nile Delta region and the northern coast of Egypt (Hassanane et al. 2010).

Physical Characteristics: Lop-eared Baladi goats have long ears that hang down to their shoulders. They have a medium-sized body with a narrow chest and straight back. Their coat colour is usually black or brown, but can also be white or spotted (Hassanane et al. 2010).

Adaptive and Special Genetic Characteristics: There is limited information in literature on the adaptive and special genetic characteristics of Baladi goats, making them a population that is poorly researched and poorly exploited. However, they are a hardy breed that is well-suited to the local environment, recognised as an important source of food and income for the small-scale farmers in Egypt (Hassanane et al. 2010).

Typical Production Systems and Production Characteristics: Lop-eared Baladi goats are raised for their meat, milk and skin. They are usually raised in small herds by small-scale farmers, are well adapted to the hot and dry climate of Egypt and survive well on low-quality feed. This breed is also resistant to many of the goat diseases prevalent in the region and classified as average milk producers, producing around 1.5 litres of milk per day (Hassanane et al. 2010).

5.5.1.10 Zaraibi

Origin and Distribution: The lop-eared Zarabi goats are part of the indigenous Nubian goats of Egypt, found in the northeast of the Nile Delta (DAGRIS 2019).

Physical Characteristics: The breed is characterised by elongated drooping ears, a convex facial profile with diverse coat colours that include brown, reddish-brown and spotted (DAGRIS 2019).

Adaptive and Special Genetic Characteristics: Information about their genetic uniqueness is not documented in literature, but we believe they share a similar genetic profile with other breeds found in the Nile Delta region.

Typical Production Systems and Production Characteristics: The breed is primarily a dairy goat and secondarily for meat. The meat is savoury, with a taste that is described as intermediate between beef and lamb (DAGRIS 2019).

5.5.1.11 Zaghawa

Origin and Distribution: Lop-eared Zaghawa goats are indigenous breeds found in the Zaghawa region of Sudan (Jnied et al. 2012).

Physical Characteristics Lop-eared Zaghawa goats have lop ears, which is a distinguishing feature of the breed. They have a medium-sized body with a compact muscular build (Nguluma et al. 2021).

Adaptive and Special Genetic Characteristics: There is a dearth of information on adaptive and special genetic features of the breed.

Typical Production Systems and Production Characteristics: Lop-eared Zaghawa goats are raised in traditional production systems where they are used for milk and meat production; they are known for their high milk yield and good meat quality (Jnied et al. 2012). However, there is a paucity of information on other production characteristics, creating room for research and production exploits with the breed.

5.5.1.12 Kalahari Red

Origin and Distribution: Kalahari Red (Fig. 5.3a, b), a commercial goat breed native to South Africa. Two lines were identified (Campbell 2003; FAO 1991). One was developed from redhead Boer goats, and another was developed from unimproved indigenous goats (Native South African and Namibian landraces). The name of the Kalahari Red goats is derived from their red coat and the *Kalahari Desert,* which spans the borders of Botswana, South Africa and Namibia. Some populations of the Kalahari Red goats are being developed in Australia, Brazil and the United States (Roy's Farm 2021), while some were imported from South Africa to Nigeria (Bemji et al. 2014).

Physical Characteristics: Kalahari Red is a large and tall goat breed (54.05 cm) with a long (69.8 cm), deep body (Pieters et al. 2009), a medium-to-large frame and strong legs. It has solid body colour shades from light to dark red-brown (Fig. 5.1a). White patches sometimes occur in offspring, as their ancestors had white and brown coats. Short, glossy hair bears little undercoat during winter. The pigmented skin is loose and supple. The horns present in both sexes are dark, round, curving backwards behind broad pendulous ears, soft brown eyes and a slightly Roman nose as found in the Boer goat (Fig. 5.18). Does have full and properly attached udders and teats. Multiple, divided, or extra non-functional teats may occur (FAO 1991; Roy's Farm 2021; Sanni et al. 2018).

Adaptive and Special Genetic Characteristics: Kalahari Red goats are extremely hardy and well adapted to free-ranging in arid and semi-arid

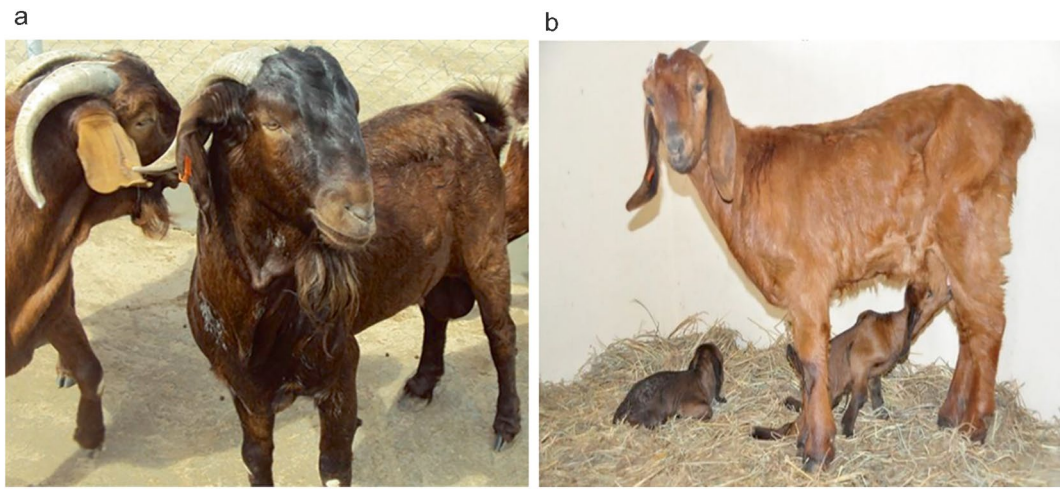

Fig. 5.3 (**a**) Kalahari Red bucks at Federal University of Agriculture, Abeokuta (FUNAAB). (Source: Bemji et al. 2014). (**b**) Kalahari Red doe and kids at FUNAAB. (Photo by O. A. Osinowo)

savanna in South Africa and the Kalahari Desert. They have strong herding instincts for protection, and their red coat provides camouflage from predators within the red soil of their native land (Roy's Farm 2021). Pigmented skin provides resistance to high radiation, enabling them to endure heat and continue to forage in hot weather. They are known to tolerate all climates (Bemji et al. 2006, 2012, 2018, 2021).

Typical Production Systems and Production Characteristics: Kalahari Red goats are managed on free-range system mainly for meat and skins. Does are calm, gentle and excellent mothers (Fig. 5.1b), both in their care of young and their protective instincts of flocking well and hiding their kids. Age at first breeding is 6 months. Does are fertile and prolific, bearing twins of equal weight, with peak fertility occurring in fall. They can breed several times a year, raising three litters over 2 years. Birth weight: 2.5 kg; weight at 6 months: 30 kg; mature live weight: 115 kg for males and 75 kg for females (FAO 1991; Roy's Farm 2021) were reported in South Africa. Kids grow fast (about 1.5 kg per week) and yield tender, delicious, low-fat meat (Roy's Farm 2021). In Nigeria, estimates of 151 days (gestation length), 2.14 (litter size) and 3.04–3.38 kg for birth weight of kids from does aged 2 to 2½ years were reported (Oderinwale et al. 2017). Omotosho et al. (2020) obtained 2.30 kg for birth weight of kids from younger does, 8.88 kg for 3-month weaning weight, while daily milk offtake and milk yield were estimated at 26.27 ml and 695.52 ml, respectively (Umejesi et al. 2016).

5.5.1.13 Kil

Origin and Distribution: Information on Lop-eared Kil goats is limited in the literature. However, available information linked the Kil goat to the Tanzania region.

Physical Characteristics: The physical characteristics of the lop-eared Kil goats are also not well documented. However, available information suggests diversity in phenotypic and genetic characteristics, especially in coat colour and ear length (FAO 2012).

Adaptive and Special Genetic Characteristics: Although there is no specific information in literature in this regard, there are suggestions that there is a strong physiological and genetic adaptability in the population to harsh environments (Silanikove and Koluman 2015).

Typical Production Systems and Production Characteristics: Information available suggests that the production indices in this goat breed are similar to those of indigenous goat breeds in sub-Saharan Africa.

5.5.1.14 Barki

Origin and Distribution: Lop-eared Barki are indigenous to Egypt, raised primarily around the Nile Delta region, particularly in the Dakahlia Governorate (DAGRIS 2023).

Physical Characteristics: The breed is referred to as the smallest Egyptian goat breed; it is of medium, compact body size with a straight profile and possesses long, drooping ears and a white or light brown coat colour (DAGRIS 2023).

Adaptive and Special Genetic Characteristics: Lop-eared Barki goats are well adapted to the hot and dry climate of the Nile Delta region. They are resistant to many common goat diseases in the area, such as contagious caprine pleural pneumonia and helminthiasis (Nguluma et al. 2021). They are also known for their high twining rate. Morphological variation exists between and within these goat populations based on qualitative data (Nguluma et al. 2021).

Typical Production Systems and Production Characteristics: Lop-eared Barki goats are raised for meat. They are usually kept in small flocks that are left to graze freely on the natural vegetation (4). The production system for these goats is not well characterised, but feed shortage, prevalence of diseases and water scarcity are the major constraints to their production in the area.

5.5.2 Short-Eared Small-Horned Goat

This goat type was introduced into North Africa (around Egypt) from the east about 3500 BC. Although their dispersal route across Africa is poorly documented, they are also found in regions including: East Africa, the equatorial

west, Central Africa and the humid hot climate of West and Central Africa. Goats of this type tend to be dwarfs, believed to be a response to natural selection on thermoregulation under the unfavourable humid and hot climate. In addition, the West African Dwarf goat has short, bowed legs attributed to achondroplasia. The distribution of this goat type extends southwards through central Africa as far as Zaire, Angola and the north of Namibia. They are also found in the western African countries of Nigeria, Ghana and Cameroon.

In Africa, breeds are often named after the main ethnic group keeping them, e.g. the Boer goat, etc. However, some of the names date from the colonial era and can take on a pejorative meaning when used in modern times, e.g. the Galla goat in Kenya. The breeds can also be named after the region in which they are found, which is sometimes synonymous with ethnicity. Types can also be referred to in a more neutral manner by naming them after an important identifying characteristic, e.g. West African Dwarf goat, the Long-eared Somali goat. The names given to the clusters reflect geographical location as much as possible, rather than ethnic group (FARM-Africa 1996).

There are many goat breeds that are classified as short-eared small-horned (Table 5.2). Three families have been identified, and these are the Small East African (SEA), Somali and Ethiopian Rift Valley families. Examples of Small East African breeds are Western Highland, Western Lowland, Central Highland, Keffa, Sudanese Hill Goat, Small East African, Mubende, Rwanda–Burundi and Kigezi (FARM-Africa 1996). They are small-horned goats with short, fine hair and variable coat colour, with some males having a short mane extending down the back and flanks. They are found in a wide range of arid and semi-arid areas and are raised in agropastoral systems where they mostly graze freely and are tethered during crop production seasons. They are mainly used for meat and skin production. FARM-Africa (1996) reported that these goats descended from the Somali Arab goats found in Somalia. The breeds in this family are distributed in various agroecological zones in East and Southern Africa.

According to FARM-Africa (1996), Somali goats comprise the short-eared Somali, the long-eared Somali and the Somali Arab breeds, while the Ethiopian Rift Valley family includes several breeds such as Arsi-Bale, Afar, Woyto-Guji, Abergelle and Worre. The breeds are believed to have originated from a Rift Valley goat breed that migrated to Ethiopia from Yemen and Saudi Arabia.

5.5.2.1 Abergelle

Synonyms: Abergale, Abergalle.

Origin and Distribution: Descendant of the Rift Valley goat type from southwest Asia and is related to Afar and Worre goat breeds. The breed is found in Ethiopia and Eritrea. The goats are kept by the Agew and Tigray ethnic groups (Gizaw et al. 2010; Yami and Merkel 2008).

Physical Characteristics: Abergelle (Fig. 5.4) is stocky, compact and well-built, with mean height at shoulders estimated at 71.4 and 65 cm for adult bucks and does, respectively. The goats have a straight to concave facial profile. Both males and females have horns, and in most cases, the horns in males are much bigger and spiral-shaped. Most goats have plain and patchy colour, and the reddish-brown colour is the most common. Spotted coat colours are also common. The hair is short and smooth in both sexes, and males have beards and ruffs. Wattles are almost entirely absent (Alemu et al. 2020).

Adaptive and Special Genetic Characteristics: The Abergelle goat is an indigenous goat population found in Ethiopia. Apart from a few resistance genes, little is known of the genetic and adaptation traits of this breed. Though not well characterised, Abergelle goats contribute to their productivity and suitability to the agroecological zones of Ethiopia, where they are found (Berihulay et al. 2019). Research has identified genetic signatures of selection in its genome (Berihulay et al. 2019) associated with adaptation to the environment and may be linked to specific traits such as size, colour, horn shape and reproductive and productive characteristics (Bertolini et al. 2018). These genetic adaptations make the Abergelle goat well-suited to walking long dis-

Table 5.2 African goat genetic resources: breed groups, subgroups and breeds

Breed group	Breed	Breed name synonyms	Location
Lop-eared goats	Nubian	Beladi, Bledi, Hassen, Langae, Sciucria, Shukria and the Sudanese Nubian	Sudan
	Sinai	Bedouin, Baladi (literally means local)	Egypt
	Swazi/Nguni	Herero, Tswana	Eswatini, South Africa, Mozambique and some places in Zimbabwe
	Berber	Algerian Berber, Libyan Mahalli, Moroccan Berber, Tunisian Berber	Algeria, Morocco, Tunisia, Libya
	Benadir	Bimal, Cherre, Tuni	South Somalia
	Wahati	Baladi (literally means local)	Egypt
	Begait	Barka, Bellenay, Beni-Amer, Hassan	Ethiopia, Eritrea and eastern Sudan
	Baladi	Egyptian; Bedouin	Egypt
	Zaraibi	Egyptian Nubian; Nuba; Theban	Egypt
	Zaghawa		Chad, Sudan
	Kalahari Red		South Africa
	Pafuri		Mozambique

tances, drought and heat stress tolerance as well as developed resistance to many common diseases in their environment, making them more resilient to the environmental conditions and production systems in Ethiopia than some imported breeds found in the same location.

Typical Production Systems, Husbandry Practices and Production Characteristics: Mixed farming and agropastoral systems and free grazing during all seasons, supplemented with crop residues in the dry season. Some localised transhumance is practised, moving flocks to graze along the banks. Abergelle goats are milked for domestic consumption. Their skin is also used to make aprons, containers, etc. According to Birhanie et al (2018), the daily milk yield of progenies of selected bucks (372 ± 14.8 ml) was significantly lower than that of base flock does (408 ± 6.72 ml). Moreover, there was significant variation of daily milk yield between the goat populations in the study districts (404 ± 14.2 ml in Tanqua-Abergele and 375 ± 7.10 ml in Ziquala) and seasons (403 ± 11.2 ml in wet and 376 ± 8.49 ml in dry). The overall mean weights at birth, 3 months, 6 months and 9 months were 2.28 ± 0.02 kg, 7.40 ± 0.09 kg, 9.48 ± 0.15 kg and 11.38 ± 0.19 kg, respectively. Comparatively, the average birth weight for progenies of selected bucks was 2.39 ± 0.02 kg, while 2.17 ± 0.02 kg was estimated for progenies of base flocks (Jembere et al. 2020). A study on carcass characteristics and sensory analysis of Abergelle goats and Abergelle cross-bred goats fed hay supplemented with a concentrate mixture showed that genotype had a significant effect on carcass parameters such as skin, foreleg and hind leg weight. However, the study found no significant difference in non-edible offal components between the two groups (Alemu et al. 2020). Abergelle goats have a high productivity rate, with a mean observed and expected heterozygosity value of 0.56, which indicates a close relatedness among the populations (Hassen et al. 2012).

5.5.2.2 Landim

Synonyms: Mozambique ('Landim' = Portuguese 'Landrace'), Small East African.

Origin and Distribution: Landrace in Portuguese resembles Mozambique Small East African goats and possibly has some early incorporation of European blood. The breed is found in southern Mozambique, south of the Limpopo and in Tete Province.

Physical Characteristics: Landim is fairly large-sized, 65 cm. Weight: male 50 kg; female 35–40 kg. Head is fairly heavy, concave profile in females, and slightly convex in males. Horns are present in both sexes: 96 percent of all animals but 31 percent have only rudimentary horns or scurs; heavier in males than females, but grow upwards and backwards in both sexes; length 11.3 cm, males 2.3 cm longer than females. Ears are medium-long, carried erect or horizontal, 13.3 cm. Toggles are present in 7 percent of both

sexes. All males have beards, but only 12 percent of females. Male has short, stiff mane extending down the back line. Neck is short and thick. Chest is well developed, girth measurement exceeding withers height considerably at all ages. Back is short. Croup is fairly long but sloping. Legs are medium in length. Colour variable is commonly dark brown (36.3%), black (23.6%), pied (23.6%), white (4.5%), yellow (4.5%) and several combinations of colours. Coat is usually short and fine.

Typical Production Systems: The main product from Landim is meat, the production system being a sedentary agropastoral and the cultivation of annual subsistence crops being the dominant farm enterprise.

5.5.2.3 Mzabite

Synonyms: Algerian Red, Touggourt, M'zab, Mozabite

Origin and Distribution: The M'zab goat, or red goat of the oases, or goat of Touggourt, is mainly found within the M'zab oases of the Ghardaia region in Algeria.

Physical Characteristics: They are medium in size, 64–67 cm high at the withers (67.1 ± 0.2 cm for males and 64.2 ± 0.2 cm for females). The coat has three colours: chamois, which is dominant, white and black. The black goat has a regular line on the spine, which sometimes has two extensions on the shoulders. The belly may be spotted black and white. The length of the hair varies from 3 to 11 cm for males and 3 to 7 cm for female (Fantazi 2004).

Adaptive and Special Genetic Characteristic: M'zabite adapts well to warm oasis regions and is resistant to certain diseases such as scrapie. Fantazi et al (2018) detected several polymorphisms in PRNP, particularly in the more ancient African *Kabyle Dwarf*, the oldest breed in North Africa. The resistant allele K222 was present at a high level in South Italian breeds and at a very low frequency in *Kabyle Dwarf,* whereas a frequency similar to other Mediterranean countries was detected in M'zabite. The overall results showed how polymorphisms in PRNP of goat populations from different areas of North Africa and the Mediterranean basin can differ in terms of variability and relative frequencies.

Production Characteristics: M'zabite is mainly raised for milk and meat. Milk yield could reach 2–3 litres per day. Its production per lactation is 460 kg for a period of 180 days. It is also a good meat breed since its prolificacy can reach 180% (Fantazi et al. 2017).

5.5.2.4 Mudugh

Synonym: Modugh

Origin and Distribution: The Short-eared Mudugh goat is an indigenous breed of Somalia and is also found in Kenya and Ethiopia (Gebreyesus et al. 2012; Muigai et al. 2016). The breed is named after the Mudugh region in Somalia, where it is commonly found (Gebreyesus et al. 2012).

Physical Characteristics: The Mudugh goat has a short, smooth coat that is mainly white (76%) with brown (9%), black (7%) and grey (7%) occasionally in spotted patterns (DAGRIS 2023; Cooper 2022). The breed has short, forward-pointing ears. They have a slim but well-muscled frame, with long legs and neck, a straight facial profile, short spiral horns and a tail typically carried high and curved. Polled animals are common. The height to withers is 24–28 inches (61–70 cm) for the Short-eared Somali and 27–30 inches (69–76 cm) for Long-eared Somali. The weight of the breed ranges from 55 to 121 lbs. (25–55 kg), with Long-eared Somali tending to be larger than the Short-eared varieties (Cooper 2022).

Adaptive and Special Genetic Characteristics: The Short-eared Mudugh goat is well adapted to the harsh environment of Somalia and other arid and semi-arid regions (Gebreyesus et al. 2012; Muigai et al. 2016). They are known for their ability to walk long distances, drought and heat stress tolerance (Gebreyesus et al. 2012). The breed has developed resistance to many common diseases in their environment, making them more resilient than some imported breeds (Muigai et al. 2016; Cooper 2022).

Typical Production Systems and Uses: The Short-eared Mudugh goat is often raised in small-

scale, family based production systems. They are used for meat, milk and other products (DAGRIS 2023; Muigai et al. 2016). The breed is an important source of income and food for many people in Somalia, Kenya and Ethiopia (Gebreyesus et al. 2012; Muigai et al. 2016). The breed is also culturally significant and plays an important role in the traditions of many African communities (Gebreyesus et al. 2012; Muigai et al. 2016) where they are found.

5.5.2.5 Ndebele

Synonyms: Bantu, Matabeleland, Matebele

Origin and Distribution: The Short-eared Ndebele goat is an indigenous breed of Zimbabwe (Gebreyesus et al. 2012). It is named after the Ndebele people, who are one of the major ethnic groups in Zimbabwe (DAGRIS 2023).

Physical Characteristics: The Short-eared Ndebele goat has a short, smooth coat that is usually black or brown (DAGRIS 2023; Gebreyesus et al. 2012). The breed has short, forward-pointing ears. They have a slim but well-muscled frame, with long legs and neck, straight facial profiles, short spiral horns and a tail typically carried high and curved. The height to withers is 24–28 inches (61–70 cm). The weight of the breed ranges from 55 to 121 lbs (25–55 kg) (DAGRIS 2023).

Adaptive and Special Genetic Characteristics: There is limited information available on the adaptive and special genetic characteristics of the Short-eared Ndebele goat, which makes this breed a poorly explored breed that requires characterisation as a priority.

Typical Production Systems: The Short-eared Ndebele goat is often raised in small-scale, family based production systems. They are used for meat, milk and other products. The breed is an important source of income and food for many people in Zimbabwe (DAGRIS 2023; Gebreyesus et al. 2012). The breed is also culturally significant and plays an important role in the traditions of the Ndebele people (DAGRIS 2023).

5.5.2.6 Somali

Synonyms: Denghier or Deghiyer, Abgal, Bimal, Dighi Yer, Dighier, Galla Habab, Maria, Modugh, Mudugh, Ogaden, Issa-Somali (FARM-Africa 1996).

Origin and Distribution: Probably related to the Arab goats in Somalia, which were introduced directly from Arabia. The related type is Long-eared Somali. *The breed is found in* northern and eastern parts of Ogaden (Jijiga, Degeh Bur and Werder), where they are kept by the Isaaq and Mijertein Somali clans and Dire Dawa, Issa and Gurgura (FARM-Africa 1996).

Physical Characteristics: The Short-eared Somali goat is smaller than the Long-eared Somali type. It has a straight facial profile, and most males bear straight (46%) upward-pointing (64%) horns. Females appear to bear more curved horns (50%), most of which point upwards (55%), but 27% are orientated backwards and 12% are lateral-pointing. Polled goats are found in 5% of males and 7% of females. There is a low incidence (6%) of spiral horns in both sexes. The Short-eared Somali goat has a short, smooth coat which is mainly white (76%) with brown (9%), black (7%) and grey (7%) occasionally in spotted patterns (12%). No ruffs were observed in either sex, but beards are present in 79% of males and 14% of females. Wattles were found in 5% of all goats. Males have a height at the withers of 64.9 cm and an average weight of 32.8 Kg against 61.8 cm in height and 27.8 Kg of weight for females (FARM-Africa 1996).

Typical Production Systems, Husbandry Practices and Production Characteristics: The animals are herded during the day by family members, usually with sheep. During the dry season, goats are watered infrequently, every 5–8 days. The goats return to the thorn enclosures at night. The average number of kids born per breeding female was 2.4. Somali goats mainly give birth to single kids (97.5%) with very few (2.5%) twins. Somali goat owners reported a tradition of selecting against twinning, and past selection appears to have been very effective (FARM-Africa 1996).

Somali goats are widely milked (Hanna ear), and milk is consumed fresh and also made into butter. The Somalis use butter for both food and medicinal purposes. Meat may be eaten fresh or preserved by cutting into slices, frying in butter

or animal fat and keeping in a container (odka). Preserved in this way, the meat can keep for up to 5 years. Odka may be given to the groom by the parents of the bride. Meat may also be preserved by air-drying strips (solei). Fresh meat may be roasted and eaten with rice (wesla). Goat skins are widely used as sitting or sleeping mats and prayer mats (harek or okedi). The Somali make water containers (karbit) and use goat skins to churn butter. The Somali also use strips of goat skin for tying firewood and constructing their houses (FARM-Africa 1996).

Genetic Characteristic: Short gastrointestinal parasites and respiratory problems, including occasional outbreaks of contagious caprine pleuropneumonia (CCPP).

5.5.2.7 Long-Eared Somali

Synonyms: Large-white Somali, Degheir, Galla, Digodi and Melebo, Boran Somali, Benadir, Gigwain.

Origins and Distribution: Long-eared Somali goats are also known as *Large-white Somali*, *Degheir*, *Galla*, *Digodi* and *Melebo*. They are probably related to the descent of the Arab goats in Somalia, introduced directly from Arabia. Long-eared Somali goats are distributed throughout the Ogaden, lowlands of Bale, Borana and southern Sidamo. They are kept by the Hawia, Ogaden, Rare Bare, Digodi clans of the Somali ethnic group and the Boran, Gabra, and Geri ethnic groups (Alemu 2015).

Physical Characteristics: Large; white; short hair. Other features: predominantly straight face; horns are curved (41% in males, 46% in females) and pointed backwards in 38% of males and upwards in 48% of females; 13% of horns in both sexes have a lateral orientation; polledness is 19% in males and 8% in females; colour is plain white (92%), brown (4%), black (3%) and grey (1%); spotted coat pattern is observed in 21% of males; ruffs occur in 21% of males but never in females; beards in 66% of males and 7% of females; wattles in 6% of males and 3% of females (Abegaz and Awgichew 2009).

Adaptive and Special Genetic Characteristic: *Typical Production Systems, Husbandry Practices and Production Characteristics:* Somali goats are extensively milked by the Somali and Boran pastoralists. Goat meat is preferred to mutton in most areas where the Long-eared Somali goat is kept.

5.5.2.8 Afar

Synonyms: Adal, Danakil

Origin and Distribution: The Short-eared Afar goat is an indigenous breed of Ethiopia (Solomon et al. 2008, 2014). It is found in very hot or arid regions of Ethiopia, where the temperature sometimes climbs to about 50 °C with low rainfall (150–300 mm). It is a valuable breed to the people of the Afar Region of Ethiopia.

Physical Characteristics: The Short-eared Afar goat has a short, smooth coat that is mainly white with brown or black markings. The breed has short, forward-pointing ears. They have a slim but well-muscled frame, with long legs and neck (Fig. 5.5), straight facial profile, short spiral horns and tail typically carried high and curved. The height to withers is 24–28 inches (61–70 cm). The weight of the breed ranges from 55 to 121 lbs (25–55 kg) (Solomon et al. 2008, 2014).

Adaptive and Special Genetic Characteristics: The Short-eared Afar goat is well adapted to the harsh environment of the Afar Region of Ethiopia. They are known for their ability to walk long distances, drought and heat stress tolerance. The breed has developed resistance to many common diseases in their environment, making them more resilient than some imported breeds (Solomon et al. 2008, 2014).

Typical Production Systems: The Short-eared Afar goat is often raised in small-scale, family based production systems. They are used for meat, milk and other products. The breed is an important source of income and food for many people in the Afar Region of Ethiopia. The breed is also culturally significant and plays an important role in the traditions of the Afar people

Fig. 5.5 A herd of Afar goats. (Anne W.T Muigai)

(Solomon et al. 2008, 2014). Its unique characteristics make it well-suited to its environment and an important part of local cultures and economies.

5.5.2.9 Zimbabwe Small Goat

Synonyms: Mashona, Small East African, Sebei, Karamoja, Tanzania, Zambian

Origin and Distribution: Found mainly in Manicaland and Mashonaland provinces, Masvingo and parts of the Midlands provinces in Zimbabwe and a wide and diverse range of environments in Kenya, Tanzania, Uganda and Zambia.

Physical Characteristics: A generalised and diverse group of goats with variable type, conformation and size of body. Adult goats stand on average 60 cm at the withers and weigh 25 kg; they are hardy animals generally used for meat rather than milk. Both sexes are horned, and horns are of variable size, ranging from 3 to 25 cm in length; shape of ears is also variable, but typical are prick ears of moderate size; wattles are fairly common; the coat hair is short, fine and smooth; in some males the shoulders, back and flanks are covered with longer hairs; and the coat is variable in colour type and pattern (Epstein 1971).

It is a small, compact and hardy goat. The goat has short ears and they are held horizontally. It appears in multiple colours. Tassels or toggles or wattles hanging under the neck are common.

Production Characteristics: Mature weights of the Mashona goat range from 25 kg to 35 kg. Kid birth weight is about 2.4 kg, with weaning weights ranging from 10 to 12 kg. Fertility is about 67.2%, and litter size is from 1.1 to 1.3. Twining rates range from 14% to 30%. The gestation period is about 5 months on average.

5.5.2.10 South Sudan Dwarf

Origin and Distribution: The Short-eared South Sudan Dwarf goat is an indigenous breed of South Sudan (FARM-Africa 1996). It is found in the southern part of the country, a region with a tropical climate and high rainfall.

Physical Characteristics: The Short-eared South Sudan Dwarf goat has a short, smooth coat that is usually black or brown. The breed has short, forward-pointing ears. They have a slim but well-muscled frame, with long legs and neck, a straight facial profile, short spiral horns and a tail typically carried high and curved. The height to withers is 20–24 inches (50–60 cm). The weight of the breed ranges from 44 to 66 lbs (20–30 kg) (FARM-Africa 1996).

Typical Production Systems: The Short-eared South Sudan Dwarf goat is often raised in small-scale, family based production systems. They are used for meat, milk and other products. The breed

is an important source of income and food for many people in South Sudan. The breed is also culturally significant and plays an important role in the traditions of many African communities. Its unique characteristics make it well-suited to its environment and an important part of local cultures and economies.

5.5.2.11 Madagascar

Origin and Distribution: The Short-eared Madagascar goat is an indigenous breed of Madagascar. It is found throughout the island of Madagascar (Ngere 1987).

Physical Characteristics: The Short-eared Madagascar goat has a short, smooth coat that is usually black or brown. The breed has short, forward-pointing ears. They have a slim but well-muscled frame, with long legs and neck, a straight facial profile, short spiral horns and a tail typically carried high and curved.

Typical Production Systems and Uses: The Short-eared Madagascar goat is often raised in small-scale, family based production systems. They are used for meat, milk and other products. The breed is an important source of income and food for many people in Madagascar. The breed is also culturally significant and plays an important role in the traditions of many Malagasy communities (Ngere 1987).

5.5.2.12 Sudanese Hill Goat

Synonyms: Sudan desert, Goat Southern Sudanese, Southern Sudan, Nuba Mountain, Ingessana, Latuka-Bari, Nilotic, Yei, Toposa, Dinka Dinka, Ingessana, Latuka-Bari, Montain, Nuba Nilotic, Southern Sudanese, Toposa, Yei.

Distribution: The goats are mainly found in South Sudan.

Physical Characteristics: In general, the Sudanese Hill goat has mixed coat colours (Fig. 5.6). Black or white with or without spots or patches were more frequent (40%), followed by black colour (31.6%), brown colour (18.33%) and white colour (10.00%). Indigenous Sudanese desert goats have a straight rump shape. About 97% of the studied goats were horned. Most had no wattle (100%) and were bearded (71.6%), 8.33% were toggled. The average body length is 56.98 cm. Horn length is 11.61 cm, which is an important self-defensive mechanism to enable them to thrive in the harsh surroundings in which they are raised. The average chest girth was 68.45 cm and longer ears of 19.28 cm (Warsame and Turyasingura 2022).

Adaptive and Special Genetic Characteristics: The breed is adapted to arid zones, extending to hyper-arid zones during transhumance and nomadic migration. Black-coloured animals are better adapted to seasonal cold weather or cold nights because the dark pigment allows them to absorb heat faster than other coat colours.

Typical Production Systems and Uses: The breed is mainly raised for meat and milk under traditional agropastoral and pastoral systems.

5.5.2.13 Boran

Synonyms: Galla; Somali, Modugh/Mudugh, Short-eared Somali, Dighier/Deghiyer/Deghi Yer, Denghier, Abgal, Ogaden, Issa-Somali, Habab, Maria, Bimal.

Origin and Distribution: The Boran is part of the Small East African group, Northern Kenya, southern Somalia and parts of southern and southeastern Ethiopia.

Physical Characteristics: The Boran is of small size (60 cm at the withers). The male weighs 30–40 kg; the female, 25–30 kg. Benadir is slightly larger. Head is fine, the muzzle is narrow, and the facial profile is convex. Horns are small, usually slender, with no marked twist, in

Fig. 5.6 Sudanese hill goat. (Photo: Y. A. Hassan)

about 97% of animals. Ears are short to medium, pricked sideways and slightly forwards and upwards. Toggles in about 5% of both sexes. Neck is medium length. Chest narrow, girth exceeding withers height by about 10%. Back is fairly long and slightly dipped. Croup is sloping, and legs are long.

Colour is brilliant white (>70% in central Somalia). Some Ethiopian goats from the Ogaden have black spotting or solid black on the head and forepart of the neck; some varieties have a black dorsal stripe. Hair is short, shiny and smooth with thin skin.

Adaptive and Special Genetic Characteristics: The Short-eared Boran goat is well adapted to the arid and semi-arid environments of Kenya and Ethiopia. They are known for their ability to walk long distances, drought and heat stress tolerance. The breed has developed resistance to many common diseases in its environment, making it more resilient than imported breeds.

Typical Production Systems and Husbandry Practices: The management systems are pastoral and agropastoral. In the Kenya Coast, about 20 per cent of farms keep cattle, but about 60 per cent have small ruminants, mostly goats. In Central Somalia, Animals are herded during the day and penned in thorn enclosures at night, kids separated from adults. Kids are allowed to suckle twice a day after milk for human consumption has been taken off. Bucks run continuously with does to ensure kidding (and milk supply for humans) all year round.

5.5.2.14 Maasai

Synonyms: Congo, Chaga, Arusha, Small East Africa

Origin and Distribution: The majority of goats in the Maasai steppe zone of Northern Tanzania are strains of the indigenous breed of Small East African goats. The Maasai steppe agroecological zone in Hai district has an altitude range of 900–1873 metres above sea level, with an average annual rainfall of 521 mm and 23.3 °C of average annual temperature (FARM-Africa 1996).

Physical Characteristics: Body weight ranged from 25.83 kg to 30.34 kg for goats aged below 2 years and above 3 years, respectively. The majority of goats had straight hairs, with beards present in 80% of bucks and 9.1% of does. Ears are short and erect, horns are present in more than 88% of the studied goat population, and about 48% of the horns were lateral and 18.1% straight. Facial profile was mainly concave, back was straight and wattles were absent (FARM-Africa 1996).

Adaptive and Special Genetic Characteristics: The breed is adapted to arid zones, extending to hyper-arid zones. Black-coloured animals are better adapted to seasonal cold weather or cold nights because the dark pigment allows them to absorb heat faster than other coat colours.

Typical Production Systems and Production Characteristics: The breed is mainly raised for meat and milk under traditional agropastoral and pastoral systems.

Twinning rate is 8.7%, bucks and does reach sexual maturity at 11 months of age, and does have their first kids at 16.7 months old. Kidding interval was 7.7 months, lactation length was 82.3 days (2.9 months), and pre-weaning kid survival rate was 77.1% and 79.9% for the dry and rainy seasons, respectively (FARM-Africa 1996).

5.5.2.15 Rwanda Goat/Burundi Goat

Synonyms: Chèvre rwandaise; chèvre burundaise.

Origin and Distribution: The Rwanda and Burundi goats are part of the Small East African group. The ‘types’ from Rwanda, Burundi and eastern Zaire are, for all practical purposes, indistinguishable. The goats are found in Rwanda, Burundi and Kivu province of Zaire and extend into southern Uganda and the extreme west of Tanzania. The ecological zones include subhumid east-central African highlands from 1200 m to 2500 m altitude in the 800 mm to 1500 mm rainfall zone. The estimated total number of goats and sheep (of which probably 75 per cent were goats) in Burundi was 1,313,000 in 1984; total goats in Rwanda were 940,000 in 1983, according to an administrative census (for

tax purposes), but a sample agricultural survey at the same time estimated 2.2 million goats (FARM-Africa 1996).

Physical Characteristics: The breed is of small size, 64 cm (60–67 cm). The male weighs 35 kg while the female is 27 kg. Horns are present in both sexes: curving outwards and backwards in males, up to 20 cm in length; females have lighter and scimitar-shaped horns; polled animals are very rare. Ears short to medium length, pricked forward and upward. Toggles are present in both sexes (14%). Most males and some females are bearded. Some males have a topknot and a mane along the whole length of the spine is almost universal in this sex. Neck is fine and medium length. Chest reasonably well rounded, girth measurement 20–25% greater than withers height. Withers level with the sacrum. Back is short and straight. Legs normally proportioned in relation to the body, front cannon bone circumference about 7–8 cm. Udder is rounded and small with short teats. Colour is very variable, whole blacks common, but many multicoloured animals. Coat is fine and short, but very few males have long hair on the hind legs (FARM-Africa 1996).

Typical Production Systems, Husbandry Practices and Production Characteristics: Agropastoral and agricultural systems are practised, verging on pastoral in Ankole/Bahima areas of eastern and lower areas of Rwanda.

Generalised flock structure for meat production has females 82.6% (65.7% weaned); males 17.4% (3.7% weaned); 51.3% of all goats in the traditional system have milk teeth only (FARM-Africa 1996).

Multiple births are very common; 61.1% single, 37.1% twin, 1.8% triplet in traditional system in north of Burundi; 54.6, 42.5, 2.8 and 0.2% for single, twin, triplet and quadruplet, respectively in large-scale traditional study in three countries combined; 41.4% single, 58.6% multiple under station management in southeast Rwanda. Litter size was 1.44 in traditional system; 1.75 on station, not differing significantly with season, but larger litters at older parities were noted. Annual reproductive rate was 1.86 on the station. For lifetime production, most females do not exceed 5 parturitions, but up to 12 recorded; average of 2.39 parturitions for 1340 does in large-scale traditional system survey. Age at first kidding was 640 ± 27.8 days on station in Rwanda, where does born as twins, kidded more than 3 months later than those born as singles and females out of older dams kidded younger than those out of junior dams. Kidding interval was 343 ± 13.8 days on station, but this is largely due to an imposed breeding season (FARM-Africa 1996).

5.5.2.16 Western Lowland Goat

Synonyms: Shankila/Shankela, Gumuz/Gumez

Origin and Distribution: Western Lowland (Fig. 5.7) goats are also known as Shankela and Gumez locally. They are derived from the mixing of types in the past. They are distributed in the western lowlands bordering Sudan in Gojam (Metekel), Wellega (Assosa) and Illubabor (Gambela). Most closely related to the Central (Fig. 5.8a, b) and Western Highland goats in Ethiopia.

Indigenous Ethiopian goat genetic resources have been classified phenotypically into 11 types. These are Abergalle, Arsi-Bale, Afar, Central Highland, Gumez, Hararghe Highland, Keffa, Long-eared Somali, North-West Highland, Short-eared Somali and Woyto-Guji (Tesfaye 2004).

Physical Characteristics: The Gumuz goat (34.7 kg) population was significantly heavier than Central Abergelle (27.9 kg) and Abergelle

Fig. 5.7 A Western lowland or Shankela doe. (Photo: ILRI)

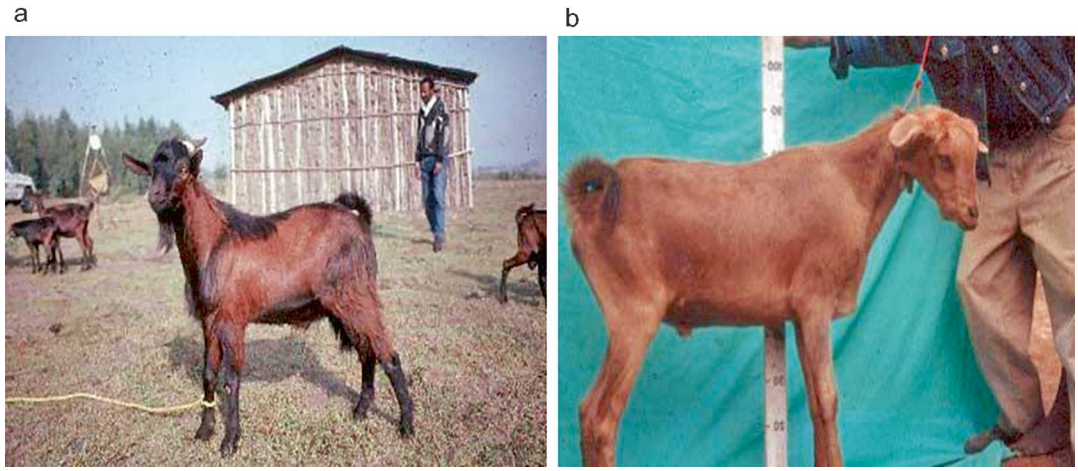

Fig. 5.8 (**a**) Keffa Central highland goat. (Photo: ILRI). (**b**) Keffa Central highland goat. (Photo: ILRI)

goat (28.1 kg) ecotypes, with an overall mean of 31.14 kg. The Begia-Medir goat, with an average height of 71 cm at withers, was significantly taller than all other goat ecotypes, while Gumuz goats were the shortest with 65 cm height at withers (Hassen et al. 2012). The goat has a straight facial profile (100%), short, smooth coat (81%), with 16% having a relatively coarse coat. The main colours are white (42%) and fawn (38%), with some black (9%) and grey (11%), occurring mainly in patches (73%). Most male goats have straight horns (85%) orientated backwards (77%). There are 12% polled males in the population. A ruff is present in 96% of all males and a beard in 70% of males. Wattles are present in 12% of all male goats.

Adaptive and Special Genetic Characteristics: The breed is adapted to arid zones, extending to hyper-arid zones. All the Ethiopian goat populations are very closely related to each other.

Typical Production Systems and Production Characteristics: Pastoral and agropastoral groups in the area of distribution use goat milk extensively. Goat meat is widely eaten. The horn is used as a musical instrument (zoombara) in Assosa. The average number of kids born per breeding female is 3.5. Western Lowland goats are remarkably prolific, with 56% giving single births, 41% twin births and 3% triplets. Quadruplets were also reported (Tesfaye 2004).

5.5.2.17 West African Dwarf (WAD)

Origin and Distribution: Synonyms for the breed include Djallonke, African Pygmy, 'Chèvre de Fouta Djallon', 'chèvre guinéenne', 'chèvre naine', Guinean Dwarf, Cameroon Dwarf or pygmy, Kirdi (southern Chad and northern Cameroon), Ghana Dwarf, Ghana Forest, Forest Dwarf, Nigerian Dwarf, Cameroon Grassland Dwarf, Congo Dwarf and Chèvre de Casamance (Wilson 1991; DAGRIS 2007). The breed is an achondroplastic dwarf with a lack of ossification at the cartilage joints, which probably evolved in response to the conditions of the humid forest zone by selection of recessive genes for dwarfism (Wilson 1991). With the exception of the Central African Republic, they are found throughout the Atlantic coastline of 15 West and Central African countries (Guinea Bissau, Guinea, Liberia, Sierra Leone, Cote d'Ivoire, Ghana, Togo, Benin, Nigeria, Cameroon, Congo, DRC, Equatorial Guinea, Gabon and Chad). According to the latter author, they constitute the only goat breed (100%) in Liberia, Sierra Leone, Congo, Equatorial Guinea and Gabon. For subtypes, many are recognised, usually by the name of the country of their location and the type of habitat, such as Cameroon grassland (Fig. 5.7), Ghana forest, Cote d'Ivoire dwarf and Congo Dwarf. Slightly larger goats than the typical WAD, such as the Mossi of Burkina Faso, goats of southern Mali and the Kirdi of southern Chad and northern

Cameroon, are also sometimes included in the main type.

Physical Characteristics: WAD goat is very short (30–50 cm), with an average height at the withers estimated at 44.74 ± 0.64 (Fajemilehin and Salako 2008). Coat colour is variable (Figs. 5.9 and 5.10) depending on region (Okpeku et al. 2011a; Wilson 1991). Dark brown with black points is common, but black, white, red, pied and mixed colours also occur. In addition to three basic colours (black, brown and white), larger face, agouti and spotting patterns with over 22 combinations have been reported in Nigeria (Bemji et al. 2012). Review by Wilson (1991) showed that the coat of WAD goat has stiff and short hair with longer hair and varying degrees of waviness in some subtypes. Horns are present in both sexes, curling outwards and backwards in males and fairly strong, while light, sharp and pointing upwards and backwards in females. Ears are short to medium length, narrow and carried horizontally. Toggles may be present in both sexes. Males are bearded with a weak mane, while females occasionally have beards, and the degree of bearding varies depending on sub-type. Neck is strong and fairly long, chest broad and deep, and the udder is small and well-shaped.

Fig. 5.9 Cameroon Grassland Dwarf. (Photo by Jules Fon)

Fig. 5.10 West African Dwarf doe at Southwest Nigeria. (Photo by M.N. Bemji)

Adaptive and Special Genetic Characteristic: WAD goat is hardy, trypanotolerant and resistant to gastrointestinal nematodes (Chiejina and Behnke 2011). They are well adapted to humid rainforest zones. Goats found in Africa can be broadly categorised into three namely; indigenous/native, exotic and composite (locally developed hybrid) types. Indigenous goats are hardy and well adapted to prevailing agroecological and environmental challenges in the regions of Africa where they are found.

Typical Production Systems and Production Characteristics: WAD is mainly raised for meat under agricultural and urban systems, while the agropastoral production system is rare. In southwest Nigeria, three types of management systems (free roaming, confined for part of the year and confined the whole year) are practised. Reproductive characteristics as reviewed by Wilson (1991) include age at first kidding: 12–18 months; Kidding interval: 210–290 days; multiple births are many, twins are very common, triplets are common with occasional quadruplets. Average litter size is 1.40–1.85 and can be more than 2 depending on parity; Oestrus cycle is 16–25 days, with heat lasting 16.4–40.0 hours; Gestation period: 142–149 days; birth weight: 1.04–1.62 kg; weights at 3, 9 and 12 months were 4.6 kg, 6.0 kg and 9.5 kg, respectively; average daily gain from birth to 90 days, 90–150 days and 150–365 days were 35 g, 20 g and 16 g respectively; mature liveweight ranged from 20 to 25 kg for male and 18 to 22 kg for female. In Southwest Nigeria, mature weights were 26.3 kg for white goats, while brown and black goats weighed 23.40 and 22.24 Kg, respectively (Ebozoje and Ikeobi 1998) Dressing percentage was 63% for a live weight of 23.5 kg; Carcass composition:

meat/bone ratio of 0.41. The carcass has more fat than dwarf sheep in the same environment (Wilson 1991). In the humid zone of Nigeria, the daily milk offtake for West African Dwarf goats was reported to be approximately 14.58 ml, with values influenced by parity and lactation stage, peaking at 36 ml on the eighth day before declining (Olalere & Bemji, 2024). Wilson (1991) reported a lactation length of 126 days with peak yield of 710 g at about 40 days; Milk composition was DM: 19.2%; fat: 8.3%; protein: 5.1%; lactose: 4.5%; energy: 123 Kcal/100 g.

5.5.2.18 Small East African/Mubende

Synonyms: Mashona

Origin and Distribution: The Mubende goat is a breed found in the sub-humid highland areas of Uganda and Zimbabwe, known for its unique black or black-and-white hair coat (Fig. 5.11a, b) in both sexes, high-quality skin and valuable meat production. The main location in Zimbabwe is in the southeast of the country; this goat is replaced by the Ndebele type (Wilson 1991). According to Onzima et al. (2018), the Small East African exists in Uganda, and in a study, reported high genetic variability of the Ugandan goat populations with sufficient genetic potential for further improvement of the breeds for heritable economic traits. The Ugandan indigenous goats are weakly differentiated, consisting of two breeds forming more uniform clusters (Kigezi and Small East African), two breeds clearly cross-bred (Karamojong and Sebei), and Mubende showing signs of gene flow from all these goat populations.

Typical Production Systems, Husbandry Practices and Production Characteristics: From a flock of traditionally managed Mashona Small East African goats monitored over a 6-year period, kids born in the hot dry season were significantly heavier at 60, 90 and 180 d (6.4, 8.0 and 10.9 vs 5.7, 6.7 and 9.2 kg, respectively) than kids born in the hot wet season. There was a steady decline in growth rates from age 15 d (60.2 g/d) to weaning age of 180 d (41.7 g/d). Overall, 19.4% of the 294 kids born during the study period exited the flocks before age 180 d. Major causes of exits were lost kids and predation, which together accounted for 61% of exits by kids. Seasonal effects on exits were mainly at ages below 30 d, where 10.3% of kids born in the hot dry season exited compared to 4.3% and 4.6% for the hot wet and cool dry seasons. Kidding intervals were 321 and 259 days. Due to the slow growth rates and long kidding intervals, the flock productivity in terms of weaned live kid weight (kg) per doe per year was low (Ndlovu and Simela 1996).

5.5.2.19 Malawian (Small Goat)

Synonym: Small East African

Origin and Distribution: This is a small breed under the Small East African goats. It is found in Malawi in various agroecological zones ranging

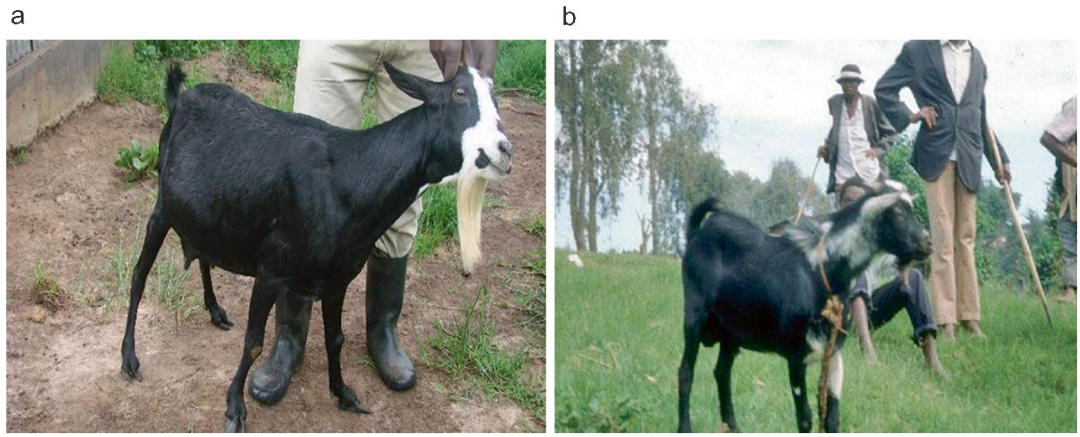

Fig. 5.11 (**a**) A Mubende doe. (Photo by D. Kugonza). (**b**) A Mubende buck. (Photo by D. Kugonza)

from semi-arid to sub-humid uplands. They are raised in agricultural systems with an average flock size of nine and mainly for meat production. They are mostly tethered during the day in cropping seasons and left on free range after harvest. They are housed at night in different types of housing. Flock structure is related to meat production.

Physical Characteristics: They are small in size, with a length of 62 cm and a weight of about 29.1 kg for females. The head is fine with a facial profile that is straight or dished. They have horns in both males and females, with pricked ears. The neck is fine and fairly long, and the chest is fairly well developed. The girth measurement is greater than the withers height by about 20%. They have a rump that is higher than the withers. The most common colours are black, black and brown, brown and red and white with a very wide variation. Some have 'Badger' and reverse badger face markings, and the hair is generally short and fine.

Typical Production Systems, Husbandry Practices and Production Characteristics: Age at first kidding was 15.6 months in the village system; 17.5 months on the ranch; 451 days (14.8 months) on the development project. Kidding interval was 44.9 weeks in the village; 35.2 weeks on the ranch; 254 days on the development project. Multiple births are common. Birth weight was 1.76 kg. Weight at 280 days was 12.2 ± 2.4 kg on the development project. Average daily gain from birth to 280 days was 36 ± 8 g on the development project. Post-partum weights were 29.5 kg in the traditional system and 28.5 kg on the ranch.

5.5.2.20 Small East Africa/Congo Dwarf/Angola

Synonym: Bahu

Origin and Distribution: The Congo Dwarf/Angola Dwarf goat is found in the eastern part of the Congo on the Upper Uele and Upper Ituri rivers, as well as near Lake Kivu. The Congo dwarf is classified under the subgroup of Small East African Meat goat. It occupies the eastern part of Congo on the Upper Uele and Upper Ituri rivers, the vicinity of Lake Kivu in Burundi, and the area north and west of Lake Tanganyika (Epstein 1971).

Special Characteristics: The short-coated Congo Dwarf goat stands at only 40–50 cm (Fig. 5.12) at the withers, but in the Savannah, it may reach a height of 60–70 cm, suggesting that its size is dependent on the environment rather than on race. It is generally characterised by a black-and-white colour pattern, less frequently by a brown or black coat; a short head with a prominent forehead; occasionally polled or furnished with short scimitar-like or twisted horns; short erect ears; absence of a beard, occasional presence of throat lappets, a large chest and a plump; very compact and well-covered body standing on short, straight or crooked legs. The milking qualities are negligible (Epstein 1971; DAGRIS 2007).

5.5.3 Short-Eared Twisted-Horned Goats

The earliest domestic goats of Africa belonged to a small generalised type (DAGRIS 2007). Ancient Egyptians received these dwarf goats and passed them to the south up the Nile Valley and across to Lake Chad before they received the specialised screw-horned goats. The centre of evolution of the screw-horned goats is not very clear. Since Egypt and India are peripheral areas of its range, the centre of evolution is speculated

Fig. 5.12 Small East African goat

to be in present-day Iran and Iraq. It is also possible that not all ancient screw-horned goats were derived from the same source. Selection is believed to have affected the forms of ears and horns and probably led to the dominance of long drooping ears. These ancient screw-horn goats have fairly long legs and short hair, and their colour was red, black, fawn, white or pied. From the northern region of Africa, the screw-horned, lop-eared type later spread to the west and south. Today, their distribution is limited to the Sahel, from western Sudan in the east, across Mali and Niger to Mauritania and Senegal in the west. Examples of goat breeds in this group include: Red Sokoto, Barguirmi Maradi, Sahalian, Sudan Desert and Sukria.

Fig. 5.13 A herd of Red Sokoto does at the National Animal Production Research Institute (NAPRI), Zaria, Nigeria. (Photo: M.N. Bemji)

5.5.3.1 Red Sokoto

Origin and Distribution: Synonyms include Sokoto Red, Kano Brown (Kyasuwa), Katsina Light Brown, Mambilla, Bornu White, Buduma (Chad), Damagaran dapple-grey and Maradi in Niger (Chèvre rousse de Maradi) (DAGRIS 2007). The breed is one of the Savanna goats with a fairly small size, suggesting the possibility of crosses with dwarf goats before selection in their current habitat. The hypothesis that a fusion occurred is supported by the relatively high prolificity of the Sokoto goat (Wilson 1991). Subtypes outside the main centres of its distribution have varied colours, such as Kano Brown, Bornu White, etc. Red Sokoto breed is mainly found in southern Niger and northern Nigeria between latitudes 12°N and 14°N and longitudes 4°N and 10°E. In Nigeria, it is common in Sokoto and Kano States.

Physical Characteristics: Red Sokoto breed is of small size, about 60 cm height at the withers (60–65 cm for males and 54–65 cm for females), but Bornu White is up to 80 cm (Okpeku et al. 2011a; Wilson 1991). Literature reviewed by Wilson (1991) shows that coat colour is deep red in Sokoto (Fig. 5.13) but lighter and occasionally almost chestnut in Maradi. Males are darker than females and may have a black back stripe. Bornu White has occasional black or brown spots on the nose, ears and around the eyes. Head is fine, the forehead is prominent, and the profile is short and straight or slightly dished. Males and females are horned (short to medium in length and somewhat heavier in males), ears are short, medium in width and carried horizontally. They are longer (semi-pendulous) in Niger and in Bornu White. Beard has profuse hair in males but is absent in females. Forehead is longer, bushier and darker in males than in females. Neck is short, thin and very mobile. Chest is rounded, legs are short, strong and well-muscled in fore and hind limbs. Tail hairs are black. Coat has fine and short hair, but males may have longer and wavier hair. Udder has good conformation, well rounded with well-spaced teats.

Adaptive Characteristic: The breed is adapted to semi-arid areas with a single rainfall season of 4–6 months duration.

Typical Production System and Production Characteristics: Red Sokoto is mainly kept by the sedentary agropastoral Hausa tribe. Flock sizes are small (<10 head), the breed is kept for meat, skins and milk. Production characteristics reviewed by Wilson (1991) include age at first oestrus (157 ± 5.92 days); Oestrus cycle (15–30 days); heat lasts for 24–120 hours in Kano Brown; Gestation period of 153 days (range 142–165) in Niger; age at first kidding (243–882 days); Kidding interval (240–343 days). Multiple births are common; 32.6% for single, 58.8% for twin, 7.2% for triplet and 1.8% for qua-

druplet at Shika (Nigeria); Litter size is 1.17–2.0 depending on parity; Annual reproductive rate was 1.50–2.00; 1.67 in Niger. Repeatability of litter size was 0.28 ± 0.07 (first to second kiddings) and heritability at first kidding (0.08 ± 0.02) by dam-daughter regression at Shika; Birth weight (1.5–2.0 kg); Weight at 12 weeks (7.6 kg) for singles and 5.7 kg for twins on station in Nigeria; Average daily gain of 7–120 days (males 63 g and females 55 g); Daily milk yield of 500–1000 g/d (545 g/d in 12-week lactation, does with twins produced 50 kg, better than singles by 20%). Daily milk offtake (14.09 ml) and milk yield (281.98 ml) were quite low within the humid zone of southwest Nigeria, where the breed is not well adapted (Bemji et al. 2021). For milk composition, total solids (18.2%); fat (4.7–7.8%), protein (3.8–4.7%); lactose (4.7%); energy (22.2 KJ/g dried milk) and 381 KJ/100 g whole milk (all values except lactose were higher in colostrum than in milk); dressing percentage was 45–50% (44.7–48.6%) for 20.5–25.0 kg live weight for Bornu White and 43.7–48.1% at 19.8–24.2 kg live weight for Red Sokoto at Maiduguri); young male castrates have 54–55%. For skins, average dry weight of skins from Nigeria and Niger is about 420 g (extra light is 250 g and heavy 625 g). Useful tanning area is 3–7 ft^2 (0.28–0.65 m^2). Red Sokoto skins are of excellent quality, known as 'Morocco' in the tannery trade. They are in demand for the fancy goods trade, particularly for gloves, high-quality shoes, patent leather and suede clothes. Skins of Kano goats are heavier and weigh 430–460 g (Wilson 1991).

5.5.3.2 Barguirmi Maradi

Origin and Distribution: The Barguirmi Maradi goat constitutes part of the West African Twisted horn goats, otherwise known as Zinder Brown, Chevre reusse de Maradi. The breed is the same as Red Sokoto goat of Nigeria and mainly found in Niger (DAGRIS 2007). They are restricted in Maradi and Tessoua Departments, while their subtypes extend to the west and east.

Physical characteristics: Phenotypically, Maradi goats of Niger are similar to Red Sokoto of Nigeria they are intermediate in size between the Sahel goat and the Djallonke (West African Dwarf), having approximately 65 cm height at withers and weigh 20–25 kg at maturity.

5.5.3.3 Sahelian

Synonyms: Synonyms for this breed include Sahel, West African Long-legged, Fulani (Peul, Peulh), Voltaique, Maure (Mauritania and northern Mali), Touareg, Arabian, Makatia (Algeria and Arab (Chad) (Wilson 1991; DAGRIS 2007).

Origin and Distribution: The breed (Fig. 5.14), according to Wilson (1991), is of the Savanna group, which includes several Saharan types from Egypt, Libya, Tunisia, Algeria and Morocco. For subtypes, local names are given, such as Gorane, Peul (Chad), Voltaïque (Burkina Faso), Nioro, Niafounké (Mali). Crosses with dwarf goats resulted in Vogan in Togo. The breed is distributed north of 12°N parallel from central Chad in the east to the Atlantic coast in the west and well into the southern Sahara and has migrated further south due to drought.

Physical Characteristics: The breed is large, with a withers height of 70–85 cm (80–85 cm for males and 70–75 cm for females) (Wilson 1991). Colour is very variable and depends on sub-type. Sahel type is mostly red or red pied, but grey, white and black are numerous (Fig. 5.14); Touareg is red pied or black pied, Maure is red pied or fawn pied, Voltaique has white (predominant) and other colour combinations. Coat is

Fig. 5.14 West African Long-legged at the National Animal Production Research Institute (NAPRI), Zaria, Nigeria. (Photo by J.C. Amabo)

short with stiff hair, except the mane, which could be 15 cm long. The head is small, fine and triangular in shape with narrow nostrils, fine lips, and large or less large supraorbital processes. Horns are present in both sexes (99.9% in Mali) but absent in Touareg. Horns in males are strong, spiral and up to 40 cm in length, sometimes horizontal, while in females they are 13 cm long, finer, scimitar-shaped, curving out and then in. Ears are long (21 cm) and wide or shorter (11 cm), pendent or semi-pendulous. Toggles and beards are common, manes are common in males, neck is long and thin and chest is narrow and shallow, with girth circumference slightly exceeding or about withers height. Back is straight with a prominent backbone. Legs are long and spindly, lightly boned with sickle hocks. Udder is elongated and divided into two halves with large teats.

Adaptive and Special Genetic Characteristics: Sahel goats are heat tolerant, long-legged and adapted for long-distance foraging in semi-arid and arid zones. Few are found in higher rainfall areas, but are not trypanotolerant and do not survive for long in forest savanna (Wilson 1991).

Typical Production Systems and Production Characteristics: The breed is managed under agropastoral, pastoral and urban settings for meat, milk and skins. Production characteristics as reviewed by Wilson (1991) include age at first kidding (275–1104 days); Kidding interval (234–291 days); Gestation period (148 days); Multiple births are fairly common with moderate litter size of 1.19–1.24 (1.34 for does of fourth and higher parities); Yearly reproductive rate was 1.49 in Mali, increasing with parity; Lifetime production of about 5 parturitions or less; Birth weight (2.2–3.2 kg); Weight for age at 90 days (7.7 kg); 365 days (20.2 kg); Adult weight was 31–50 kg (male 40 kg; female 27 kg); Daily milk yield (600–1500 g/d); Lactation length was 134.7 ± 5.6 (54–155 days); Milk composition: DM (12.7%); fat (3.9%); lactose (4.6%); density (1.030); Dressing percentage: castrates (49.4%) for 26.7 kg live weight, entire males (48%) for 27.4 kg and females (48.1%) for 27.8 kg. Estimates varied depending on environmental conditions.

5.5.3.4 Sudan Desert

Origin and Distribution: The breed is alternatively called Sudanese Desert, originating as Savanna type, similar to West African Long-Legged (Wilson 1991). It is common in dry areas of the Republic of Sudan, north of 12°N, while north of 10°N in Darfur, western Kordofan and also in some parts of Eritrea and westwards in Chad. Intermediate types with small forest goats are found at the southern limit in Sudan.

Physical Characteristics: The breed has a large size, with 65–85 cm height at the withers (Wilson 1991). Coat colour varies, including white (Fig. 5.15), black, greys (common), and mixed (black back stripe in dark colours and grey in light colours). Coat is short and fine. Some, especially Zaghawa, have longer hair which may cover the whole body or be limited to hindquarters and legs. Head is fine with a flat forehead and straight or a little dished profile. Horns are present in 95% of both sexes. They are long (35 cm), large, twisted and flattened in cross-section in males, projecting outwards or backwards, while in females they are finer, curving upwards and backwards. Ears are lopped and medium to very long (12–20 cm). Toggles are present in 15% of both sexes. Both sexes have beards, which are very bushy in males. Males may have a mane to the shoulders or extending the whole length of

Fig. 5.15 Sudanese Desert goat. (Photo: Y.A. Hassan)

the back, but sometimes present in females. Neck is short, chest shallow and pinched, back is short and straight, croup is very weak and sharply sloping with a low tail. The legs are long and poorly boned.

Adaptive Characteristic: The breed is adapted to semi-arid zones, extending to hyper-arid zones during transhumance and nomadic migration.

Typical Production Systems and Production Characteristics: The breed is mainly raised for meat and milk under traditional agropastoral and pastoral systems. The meat is more tender and juicier than many domestic breeds found in the region (Fadlelmoula et al. 2014). Production characteristics as reviewed by Wilson (1991) include: Age at first kidding (290 days); Kidding interval is 238 ± 41 days (Southern Darfur traditional system); 9 months (Kordofan); Multiple births (numerous) with a litter size of 1.57 (1.30 in primiparous does and 1.68 in multiparous); lifetime production is 9–10 kids (2.41 annually) in Southern Darfur and 4–7 in Kordofan; Birth weight (2.13 kg), single weighed 2.27 kg (male 2.30 kg, female 2.25 kg); twin weighed 2.05 kg (male 2.03 kg, female 2.07 kg); triplet weighed 1.82 kg (male 1.88 kg, female 1.73 kg); weight for age at 4 weeks (4.8 kg), 13 weeks (9.9 kg), Average daily gain from birth to 13 weeks (86.9 g), mature weight for male (40–60 kg); female (32.7 ± 5.22 kg); dressing percentage for entire males is 48.2% (44.2–52.8%) at live weight of 34.7 kg and castrates are 51.2% (46.6–33.1%) at live weight of 35.8 kg in Southern Darfur traditional system.

5.5.4 Exotic Goat Breeds

In general, goats not found resident in a location as described above, but imported from another region or from outside of the continent, are generally referred to as exotic goat breeds. European goats imported with the aim of so-called upgrading or improvement of indigenous goats fall into this group. Majority of these are characterised by a long and thin neck and may have horns. Their sizes usually vary from 85 to 90 cm. The body is narrow with a sharp back, with a short and sloping rump, and with high limbs. may have horns or be polled. These improvement programmes, if carried out correctly, should produce unique breeds like the ones listed in the sections for the **developed goats**, with higher production and productivity. However, when done indiscriminately and randomly without genetic records and proper monitoring, they become the source of genetic dilution and erosion of valuable local gene pool.

5.5.4.1 Angora

Synonyms: Ankara-Kecisi, Tiftik-Kecisi, Mohair goat, Sybokke (South Africa)

Origin and Distribution: Angora goat (Fig. 5.16) originated in Turkey (Özgecan and Ertuğrul 2012), from where the animals were exported to Europe in the sixteenth century and in 1838 to South Africa to establish a mohair industry without sacrificing body weight (Visser and Van Marle-Köster 2014). However, currently, this breed is widespread in many countries worldwide, including Kenya, Lesotho and Egypt from African countries (Visser and Van Marle-Köster 2014).

Physical Characteristics: Angora or Ankara goats are known for their mohair production, but they are also used for meat. They have medium-sized, horned, heavy and drooping ears. Have different coat colours but are dominated by white,

Fig. 5.16 Angora doe with its kid (Visser and Van Marle-Köster 2018)

and some goats also have black, brown, or grey coat colours. They have uniform fleece regarding the length and fineness, with good lustre, solid style and good character. Male and female Angora goats can produce up to 5.4 and 3.6 kg of skirted fibre per year, respectively. Hair length ranges from 13 to 25 cm. Mature buck weighs 45 kg and does weighs 35 kg, height: male 61 cm and female 51 cm (Özgecan and Ertuğrul 2012).

Adaptive and Special Genetic Characteristic: Angora goats are well-suited to harsh and semi-arid environments. They have high genetic diversity within populations (H_E), ranging from 0.371 in the South African population to 0.397 in the Argentina population (Visser et al. 2016). Hence, goats that are kept geographically in different countries are genetically distinct due to country-specific selection and breeding strategies. Candidate genes such as keratin-associated proteins (KAP1–KAP9) and intermediate filament proteins (KRT genes) play a functional role in the expression of fibre quality (Visser and Van Marle-Köster 2014). Marker-assisted selection for mohair traits (e.g. fleece weight, fineness, length of the fibre, etc.) using these genes and growth traits in combination with accurate estimated breeding value information could lead to a rapid genetic improvement for the Angora goat breeds.

Typical Production Systems, Husbandry Practices and Production Characteristics: Angora goats are good browsers and love grazing and eating green grasses, corns, plants, etc. They also generally eat a lot of roughage that includes weeds, bark, leaves, or woody shrubs. In South Africa, Angora goats were primarily farmed under extensive production systems, but currently, the breed is also managed under an intensive production system for the purpose of mohair production (Visser and Van Marle-Köster 2014).

Limitation and Challenges Breed Use and Classification: In the past 50 years, limited new genetic material has been available due to restrictions on imports and exports in countries like South Africa. Introduction of a new gene pool of the same breed but from other countries could improve their genetic diversity and productivity.

5.5.4.2 Damascus

Synonyms: Aleppo, Baladi, Chami, Damascene, Halep or Shami

Origin and Distribution: Damascus goat (Fig. 5.17a, b) is a native breed of the Middle East (Cyprus, Syria and Lebanon). It is believed that these goats were taken by the British to Cyprus, the place where the goat got the name Damascus. It is developed through crossbreeding of Nubian (African origin) and Jamnapari goats of India and belongs to the Nubian group (ESGPIP 1971). This breed is also introduced to African countries like Egypt and Algeria.

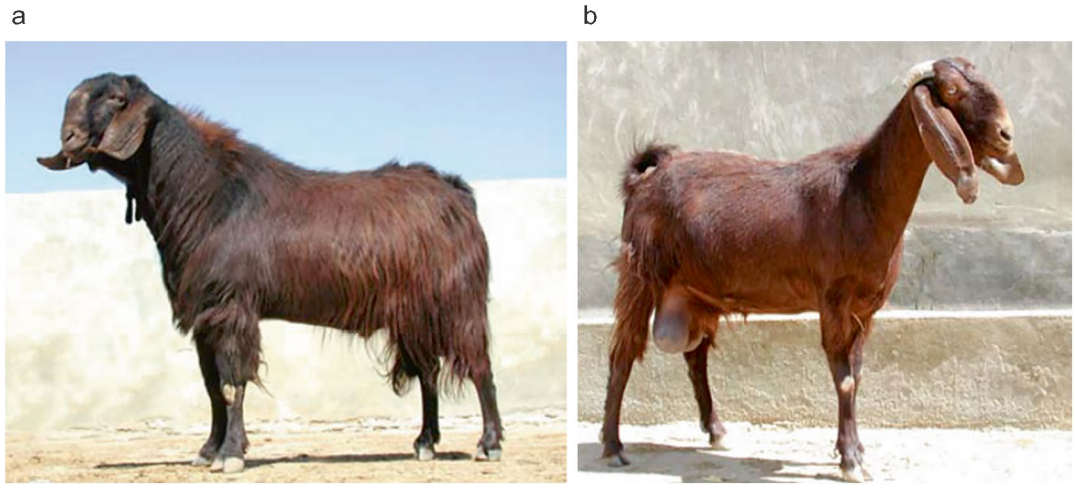

Fig. 5.17 (**a**) Damascus buck. (ESGPIP 2008). (**b**) Damascus doe (ESGPIP 2008, 1971)

Physical Characteristics: Damascus goat breeds are used as a multipurpose breed. They are prolific, and a doe can give birth to two kids per doe on average, but three and four kids per doe are also common. Birth weight ranges from 3.5 to 5.5 kg depending on the birth type, season and sex. At an early age, kids have a normal face. But at a later stage, they change from beautiful to a monster face. They are also known as noble creatures in the Middle East and have a long neck, legs and hair, a large body size, long (27–32 cm) and drooping ears and a small head. They have a unique look, with an almost scrunched-up face. Their head has a convex bridge, polled (81.2%), coat colour varies from brown (42%), grey (27%) and black (21%), which resulted from continuous selection of the preferred coat colour (Halima et al. 2016). An average body weight of a mature buck and doe is 75 ± 5 kg and 65 ± 5 kg, respectively. Height at wither is 80 cm for males and 74 cm for females, with body circumference ranging from 97 cm to 99 cm.

Adaptive and Special Genetic Characteristic: The most desirable feature of Damascus or Shami goat is its adaptative to high temperatures and suitablity for breeding in lowland areas (Tatar et al. 2019).

Typical Production Systems, Husbandry Practices and Production Characteristics: The breed is considered one of the best dual-purpose (meat and milk) breeds of the Middle East countries under a semi-intensive or intensive production system. It is not successfully raised under an extensive grazing system. Hence, it requires an improved management and feeding environment to express its full genetic potential. They are good milk producers and could produce 1.9 litres of milk per day on average. They can reach puberty within 5–10 months, depending on the feed availability and other management factors, including veterinary service and housing.

Limitation and Challenges Breed Use and Classification: Some Damascus goats have long protruding lower jaw that makes them difficult to graze and nurse.

5.5.4.3 Toggenburg

Synonyms: Swiss Alpine, Togg, Toggenburger Ziege, Chèvre du Toggenbourg, Capra del Toggenburgo

Origin and Distribution: Toggenburg goat was developed in Switzerland for the first time (Bosman et al. 2015). They are developed through crossing of Appenzell and Chamoisee goats (ESGPIP 1971). Currently, it is distributed worldwide. It is a dairy goat type.

Physical Characteristics: Toggenburg goats are a compact, robust, dairy-type animal (that is, with a dished or straight facial line and wedge-shaped body). They have short or medium in length, soft, fine and lying flat hair. Their coat colour is solid, varying from light fawn to dark chocolate with no preference for any shade. They are usually slightly smaller than other Alpine breeds. Adult bucks and does weigh 75 kg and 55 kg, respectively. Height at the wither ranges from 66 to 91 cm (mean 85 cm) and 63.5 to 91 cm (mean 75 cm) for adult males and females, respectively.

Adaptive and Special Genetic Characteristic: The Toggenburg are adaptable to different climatic conditions but best performed in cooler climates and less suited to tropical climates (Burren et al. 2016). It is better adapted than other exotic dairy breeds, such as Saanens or Anglo-Nubians.

Typical Production Systems, Husbandry Practices and Production Characteristics: The Toggenburg goats are adapted to grazing in rough pastures or an alpine environment (Burren et al. 2016). They are good milk producers and could produce from 1 to 3 litres of milk per day, depending on feed quality and accessibility. Jackson et al. (2014) also reported that Toggenburg goat breeds are better milk producers in sub-humid areas (0.3 litres of milk per day better) than semi-arid areas. This has mainly happened due to the availability of feed resources both in quality and quantity. However, they are also suitable for stall feeding. Their milk yield and flavour are also better if they can range extensively on a variety of forages.

Limitation and Challenges Breed Use and Classification: Handling these goats requires experience and expertise. They are active and aggressive. Hence, they are tough to handle, and they can even break out of their fences.

5.5.4.4 Saanen

Synonyms: It has different names in different countries. Example: Chèvre de Gessenay (French) or French Saanen, Saanenziege (German), Capra di Saanen (Italian), Israeli Saanen, British Saanen, Russian white, Sable Saanen (New Zealand),

Origin and Distribution: Saanen goat is one of the most important dairy goat breeds, originating in Switzerland, from the Saanen Valley (De Vasconcelos et al. 2021). They are distributed in more than 80 countries of the world (FAO 2007). These goat breeds are used to develop other dairy goat subtypes such as German, British, Dutch, French, Israeli, Russian, Australian and American Saanen breeds (ESGPIP 1971).

Physical Characteristics: They are characterised as all-white or all-cream coat colour, short hair with occasional black spots on the udder, ears and nose, a straight face, short and pointed ears (ESGPIP 1971). Horns are sabre-shaped and pointed backwards. Adult males weigh 85 kg and females 60 kg; height is 90 cm for males and 80 cm for females (Pesmen and Yardimci 2008).

Adaptive and Special Genetic Characteristic: The Saanen goats are adaptable to temperate and wet environment (Devendra and Haenlein 2016). They are sensitive to excessive sunlight and perform best in cooler conditions. The provision of shade is essential.

Typical Production Systems, Husbandry Practices and Production Characteristics: Saanen goats are mainly managed under an intensive production system. Saanen goats can produce an average milk yield of 700 kg within 260–280 days of lactation length. But they can produce more than 1000 kg of milk yield in some productive does, depending on the husbandry practice taking place from country to country. Because of their high-level milk production and low level of milk fat content, they are compared with Holstein Friesian dairy cattle breeds. The milk fat content ranges from 3% to 4%. However, this milk composition and yield can be affected by environmental factors such as feed, season, climatic conditions, etc.

5.5.4.5 Anglo-Nubian

Synonyms: Nubian (USA), Nubia (North-eastern Africa)

Origin and Distribution: The Anglo-Nubian goat originated in the United Kingdom (FAO 2007). It is all-purpose breed known for meat, milk and hide production. The breed was developed through the crossing of a British goat with bucks of Indian (Jamnapari) and African (Zaraiby goat from Egypt breeds with Nubian and Damascus ancestry) (FAO 2007). The breed is distributed in more than sixty countries.

Physical Characteristics: Anglo-Nubians are characterised by large body size, pride, grace, long legs, either polled or small horns, a convex facial profile and pendulous ears. They have different coat colours but commonly black, chestnut, cream, fawn or white with solid and pattern coat colour. They are prolific, docile and friendly in nature. Adult males weigh up to 140 kg (average 79 kg) and females up to 110 kg (average 61 kg); height is 90 cm for males and 80 cm for females. Birth and weaning weight of Anglo-Nubian kids are recorded as 2.54 kg and 13.12 kg, respectively (Lele et al. 2018). However, birth and weaning weight can be affected by season and year of birth, sex of the kid, type of birth and parity.

Adaptive and Special Genetic Characteristic: Anglo-Nubian goats are well adapted to hot climatic conditions and tolerate frequent weather changes. They have been used in grading-up programmes in many tropical countries to increase the milk and meat production of local breeds.

Typical Production Systems, Husbandry Practices and Production Characteristics: Anglo-Nubian goats have an extended breeding season, so they can produce milk year-round. They provide an average milk yield of 260 ± 129.11 kg within 191 days of lactation length (Lele et al. 2018). The author also added that the minimum and maximum daily milk yield varies from 0.24 to 3 litres. These goats are not

heavy milk producers, but they produce quality milk with an average butterfat content of ~5% and protein content of ~4%.

5.5.4.6 Alpine

Synonyms: Alpine polychrome, American Alpine or American Oberhasli, French Alpine, German Alpine or German Fawn, British Alpine, Swiss Chamoisee, etc.

Origin and Distribution: Alpine goats are mountain breeds of Switzerland and are a good dairy goat type (Devendra and Haenlein 2016).

Physical Characteristics: The Alpine goat breeds have different coat colours, which leads to the formation of distinctly separate breeds. Their coat colour can range from white or grey to brown and black. They have medium-to-large size, hair is medium to short, alert, graceful, erect ears, face is straight and prolific goats (1–3 kids at a time). Mature Alpine male goat weighs 77 kg and female 6 1 kg; height at withers 81 cm for male and 76 cm for female.

Adaptive and Special Genetic Characteristic: The Alpine goats are hardy and adaptable and succeed in any climate conditions while maintaining good health and excellent production.

Typical Production Systems, Husbandry Practices and Production Characteristics: The Alpine goat can be managed under extensive, semi-intensive and intensive production systems, but their production performance is higher in intensive production compared to the two production systems. This breed is extremely well known in the dairy industry for their docile temperament, high-quality milk production and long lactation length. On-farm research conducted in Kenya indicated that an adult Alpine dam aged 5–6 years can provide ~3 litres of milk per day, whereas 2–4.9 years old gives 1.7–2.7 litre (Monica et al. 2014). These goats were supplemented with concentrate feed and minerals. Therefore, milk yield is affected by the age of the dam and feeding practice. They also reach sexual maturation within 4–5 months for buck kids and 5–6 months for doe kids. However, doe kids should not be bred until they are at least 34–36 kg in weight.

5.5.4.7 Status of the Exotic Goat Breeds in Africa

In Africa, most of the goat breeds/populations are dual-purpose breeds, mainly kept for meat production and at medium to low levels for milk production. Even though there are some dairy- or meat-type goat breeds, no genetic improvements have been made so far and managed under an extensive production system. As a result, their production performance, in both meat and milk, is low. To improve their production performance in a short time at a low cost and reduce poverty, exotic goat breeds, mainly dairy goats, were introduced to African countries by non-governmental organisations and some Universities and research institutions. However, in most African countries, except in Kenya (in some breeds: e.g. Saanen) and South Africa, they were unsuccessful and unsustainable. The main reasons were: these exotic breeds were imported and introduced to beneficiaries without any clear justification, lack of adequate planning, such as a structured breeding programme and the development of useful technologies, and efficient management of high-producing animals, such as the use of concentrates, veterinary service, housing, etc. Beneficiaries did not clearly understand the nature of the exotic breeds and lacked participation in decision-making. A harsh environment is also another factor for the unsuccessfulness of the exotic goat breeds in Africa. Indiscriminate crossbreeding also poses a threat to the local genetic resources. Hence, livestock professionals and politicians do not have a common sense of understanding and do not fully participate in the genetic improvement programme of the local goat breeds and their sustainability.

5.5.5 Composite Goat Breeds

The need for specific products in goats and market demands for quality and improved quantity of certain products motivate goat farmers to develop novel goat types through crossing different local breeds and/or crossing local with imported breeds (so-called upgrading). While this has been

responsible for the production of novel goat types of important value, indiscriminate, unguided ventures only result in undue dilution and erosion of local gene pools. In the following section, we mention some successful, well-guided goat types developed in Africa and their uses.

5.5.5.1 Arabi

Origin and Distribution: The Arabi goats are also known as Arabia and Sahelian. It is a variety of Sahelian goats. There are two subtypes of Arabi goats, a sedentary and a transhumant type. They are found distributed in the high plateau and Saharan areas of Algeria.

Physical Characteristics: The sedentary type has longer hair (14–21 cm) compared to the transhumant type (10–17 cm). Predominant colours of the sedentary type are black, pied black and brown. Other coat colours include black, grey or chestnut. They have long ears and are either horned or polled.

Adaptive/Special Characteristics: This breed is highly susceptible to trypanosomiasis and can be reared only in areas not affected by this disease. It is a very hardy breed.

Productive Characteristics: Body weights at birth and adult age for males/females were recorded to be 2.5/2.0 and 60/40 kg, respectively. The average kidding interval and litter size are reported to be 80% and 1.3 kids per kidding, respectively. The females produce 0.5–1.0 litres of milk per day and a total of 220 litres over a lactation period of 120 days. The breed is mainly used for milk production. The population is considered safe.

5.5.5.2 Pafuri

Origin and Distribution: The Pafuri lop-eared goats found in South Africa are a sub-type of the Xhosa goat breed (Magoro et al. 2022). The Pafuri resulted from the crossing of imported Boer males on indigenous Landim females. The Boers were introduced from the northern Transvaal of South Africa in 1928. The breed is restricted to a small area known as Pafuri in southwest Mozambique, near the border with South Africa and Zimbabwe. This area has a semi-arid to arid subtropical climate with annual unimodal rainfall of less than 400 mm. The production system is agropastoral to transhumant.

Physical Characteristics: This goat breed is characterised by long, drooping ears, with a medium-sized body with a straight back and deep chest, and varied coat colour, but brown or black with white markings are typically common (Magoro et al. 2022). Large body size, with males weighing up to 60 kg and females up to 43 kg; convex facial profile; horns well developed and diverging in males, but smaller and scimitar-shaped in females; ears are lopped or semi-lopped with rounded tips; both males and females are bearded; coat colour is variable, and the coat hair is short.

Adaptive and Special Genetic Characteristics: Adaptive traits of these indigenous goats, including the Xhosa breed, are important for climate change and affordable maintenance (Magoro et al. 2022). Studies indicated healthy and high levels of genetic diversity in these indigenous goat populations of South Africa. However, there is a need for further research to identify genes associated with production and adaptive traits in indigenous goats (Baenyi et al. 2020).

Typical Production Systems and Production Characteristics: Goat production plays an important role in the livelihood of small farming communities in South Africa. The production potential of the indigenous goat ecotype in South Africa is high, and they are well adapted to local conditions (Magoro et al. 2022). Among sub-Saharan countries, the production system is more diverse in South Africa than most, with both extensive and intensive systems (Baenyi et al. 2020) in goat production. The milk production of this indigenous ecotype, like in most sub-Saharan goat types, is low with potential for improvement through selective breeding and improved management practices (Baenyi et al. 2020). There is also a need for conservation and sustainable utilisation of indigenous goat ecotypes, particularly in South Africa, where improvement emphasis is more on cattle than on goat (Magoro et al. 2022).

Productive Characteristics: Body weights at birth, yearling age, 18 months and adult age were

recorded to be 2.4, 16.7, 25.8 and 43–60 kg, respectively. The age at first kidding and litter size are reported to be 35.1 months and 1.1 kids per kidding, respectively. The females produce 0.3–0.4 litres of milk per day and a total of 50 litres per lactation period. According to a report in 1991, the population in Mozambique was less than 100 animals. The breed is thus considered critically at risk.

5.5.5.3 Tanzanian Blended Goat

Origin and Distribution: The Tanzanian Blended Goat is also known by the common names Blended and Malya blended. The breed was developed and stabilised as a composite breed in the late 1960s at the Malya Livestock Research Centre in Tanzania. It is constituted of 55% Kamaria, 30% Boer of South Africa and 15% of indigenous stock.

Physical Characteristics: They have large pendulous ears and resemble the Angol-Nubian breed.

Productive Characteristics: The breed is kept mainly for meat production. Body weights at birth and weaning age were recorded to be 2.6 and 12.2 kg, respectively. The average age at first kidding, kidding interval, twinning rate and litter size are reported to be 25.5–27.3 months, 261 days, 29% and 1.3 kids per kidding, respectively. The females produce 153.3 litres of milk with a butterfat content of 3% over a lactation period of 215.6 days. At slaughter, the males produce a carcass with a dressing percentage of 48%.

5.5.5.4 Vogan

The Vogan is reported to be a cross of the Djallonke with the Sahel goat from southern Togo and neighbouring Benin in the vicinity of Vogan, Aneho and Tabligbo districts. The area has a sub-humid to humid climate with a long unimodal rainfall. The production system is principally urban. The goat is characterised by horns that are triangular in males, loosely spiralled and 30–40 cm long; only 5.6% of them carry small horns; long neck; coat colour is variable, with red and black pied animals being the commonest; the hair is short.

5.5.5.5 Makatia

Origin and Distribution: This breed may be the result of a crossing between the Charkia (an Oriental exotic breed) and the long-haired Arabi goat from the Ouled Nail region. It is a variety of Sahelian goats. Found mostly in the high plateau in the northern regions of Algeria.

Physical Appearance: Large-sized animals; long and drooping ears; grey, beige, white or brown coat colour; toggles and beards common.

Adaptive/Special Characteristics: This breed is highly susceptible to trypanosomiasis and can be reared only in areas not affected by this disease. However, it is a very hardy breed.

Productive Characteristics: The breed is mainly used for milk production. Body weights at birth, yearling and adult age for males/females were recorded to be 3.0/2.5, 18–25, and 50/34 kg, respectively. The average kidding percentage and litter size are reported to be 90% and 1.5 kids per kidding, respectively. The females produce 1–2 litres of milk per day for a period of 210 days.

5.5.5.6 Boer

Origin and Distribution: The Boer goat (Fig. 5.18) is also known by other common/local names, including Africander, South African Common, Boer goat Kalahari and Boerbok. The breed was developed by Dutch settlers at the Cape mainly out of the indigenous Bantu stocks through selection for improved meat production since the 1920s although the name Boer was used in the mid-nineteenth century. Subsequently, goat breeds of European and Indian origin were used to upgrade the breed standard. The lop ears and often convex facial profile of the Boer may have arisen from Indian breeds (e.g. Jamnapari) imported during the eighteenth and nineteenth centuries. The breed society for the 'improved Boer' was established in South Africa in 1959 to improve the breed, to establish breed standards and to develop training, inspection, promotion and marketing capacity. These animals were kept in thornveld areas for bush control.

South Africa is the main location. The breed has been exported to Lesotho, Swaziland, Botswana, Mozambique, Zimbabwe and Namibia. Small populations were also imported

Fig. 5.18 Boer goat

to Kenya, Burundi, Tanzania and recently, Ethiopia. The breed is also distributed throughout the world in 43 other countries. The total population might be about 5 million, about 2.2 million of which are 'improved'. The improved Boer performs best in arid areas of South Africa, where the production systems are agropastoral, pastoral and ranching.

Physical Appearance: A red-headed, large-framed goat with a white body; droopy ears; strong and moderate-length horns, which are placed moderately apart with a gradual backwards curve; a beard is present in males (Fig. 5.18).

Adaptive/Special Characteristics: Boer goats are the most sought-after meat goat breed in the world. They are good browsers that can be used to control bush and weeds; have excellent-quality skin; low-fat, tender and tasty meat at a young age; also produce good quality white cashmere in small quantities. The breed is highly fertile with multiple births, including triplets and quadruplets, and is a non-seasonal breeder. It has an exceptional ability to withstand and resist diseases such as blue tongue, prussic acid poisoning and, to a lesser extent, enterotoxaemia (pulpy kidney). It is also less susceptible to infections caused by internal parasites as the breed prefers to graze above the ground.

Productive Characteristics: Body weights at birth, weaning and adult age were recorded to be 3.2, 24.9 and 50.7 kg, respectively. The age at first kidding, kidding percentage, kidding interval, twinning percentage and litter size are reported to be 15 months, 82.4%, 357.5 days, 65.9% and 1.6 kids per kidding, respectively. The females produce 2.0 litres of milk per day with a fat percentage of 5.7% and a total of 118.4 litres over a lactation period of 102 days.

Boer goat is primarily used for meat production. The population in South Africa in 1991 was estimated at 5000,000.

5.5.5.7 South African Savannah Goat

Origin and Distribution: The Savannah goat breed was developed in South Africa in the 1950s by breeding Boer goats for their meat quality (Chapman et al. 2022; UNEP-WCMC, IUCN 2016). Although the real origin of this breed is murky, it is generally attributed to a ranch in South Africa near the Vaal River (FARM-Africa 1994). Since the 1990s, Savannah goats have been imported to the United State (FARM-Africa 1994).

Physical Characteristics: Savana goats are large-framed, well-muscled breed primarily used for meat (FARM-Africa 1994). They typically have white coats, as the dominant coat allele. However, their skin, horn and hooves have black pigmentation to protect from the sun (FARM-Africa 1994).

Adaptive and Special Genetic Characteristics: Savannah goats are bred for their white coat, black skin and ability to withstand harsh savannah conditions like direct sunlight, changing temperatures and drought (Chapman et al. 2022). They eat plants that other flock and herd animals will not and have good reproductive traits: high fertility, mothering ability and milk production, a high twinning rate, and their kids have a good growth rate (FARM-Africa 1994).

Typical Production Systems and Production Characteristics: The Savannah goats are used in diverse goat production systems in many African countries.

5.6 Characterisation of Genetic Diversity in African Goats

5.6.1 Early Molecular Genetic Studies on African Goat Populations

Domestication gave rise to a great diversity in goats across the world, with Africa being home to the largest diversity (Stella et al. 2018; Paim et al. 2019; Colli et al. 2018; Selionova et al. 2021; Michailidou et al. 2019). Molecular and archaeological evidence suggests that African goats have a genetic affinity with Asian goat populations (Paim et al. 2019; Colli et al. 2018). African goats, however, have higher diversity, occasioned by their evolution of resistance to diverse climatic and environmental features that characterise the continent and the presence of very few improvement programmes tailored toward speciality production on the continent (Paim et al. 2019). Diversity in different populations was classified using different indices (Colli et al. 2018; Michailidou et al. 2019). Genotypic information housed in the DNA is unique not only for populations but also for individuals. The need to verify phenotypic classification with molecular data is borne from the fact that many local breeds bare very close semblance. Thus, molecular characterisation of goats and other livestock to determine what is original to, or imported to, a location is very important (FAO 1986b, 2012). Furthermore, molecular genetic tools are also very useful in the determination of the maternal and paternal origin of an animal, tracing poached and stolen animals and much more (FAO 1986a, b).

Molecular genetic characterisation studies involve the study of genetics at the molecular basis, leveraging genetic information housed in deoxyribonucleic acid (DNA) of living organisms. Microsatellite markers and mitochondrial DNA (mtDNA) markers were among the first sets of molecular markers used in goat genetic studies in Africa. Prior to this, blood protein markers, including haemoglobin and serum proteins, were used. Multiple maternal origins of the mitochondrial DNA (mtDNA) hypervariable region (Luikart et al. 2001) is among the foundational information that first classified global goat populations by lineages into A and B, based on unique haplotype grouping. Lineage B was found to be mostly Asian, and a few individuals in lineage were assigned Sub-Saharan African, including Namibia (Naderi et al. 2007) and South Africa (Awotunde et al. 2015). Over the years, more studies using the molecular characterisation approach have been carried out in different parts of the world, including Africa, to delineate indigenous from imported goat types using phylogenetic trees.

Phylogenetic study conducted to determine the relationship between the West African Dwarf, Red Sokoto and Karahari Red suggested *Capra aegagrus* as their wild ancestor (Awotunde et al. 2015). Using the same techniques, indigenous Nigerian goats have been regrouped into demographic types as northern and southern goat breeds rather than the initial phenotypic typing into three breeds (Ahmed et al. 2017). In another study by Tarekegn et al. (2019), shared haplotypes were observed between goats in Cameroon, Mozambique, Namibia, Zimbabwe, Kenya and Ethiopia, with an indication of an initial dispersion of goats to Cameroon and central Africa from northeast Africa following the Nile Delta, with autosomal genomic DNA analysis corroborating a common origin for Moroccan, Ethiopian and Iranian goats. Molecular characterisation has even improved beyond mere phylogenetic assay of selected regions of the DNA. In recent times, with the reduction in the cost of sequencing and availability of the technology in Africa, though not easily found everywhere, molecular characterisation has taken the form of genomic exploration as well.

5.6.2 Genomic Characterisation of African Goat Breeds

High-throughput sequencing platforms and chip sequencing have been carried out on some African goat breeds (Monua et al. 2020; Okpeku et al. 2011b, 2017), shedding more light on the genetic architecture and population structure,

determining the evolutionary genetic basis for adaptation to diverse environments, and providing insight into functionally important genetic variants (Andersson and Georges 2004) within and across breeds, Contributing to a better understanding of population genetic structure in goats (Monua et al. 2020; Okpeku et al. 2011a, b, 2016a; Sanni et al. 2018), coat colour genetics (Adefenwa et al. 2013), genetics of immune response (Yakubu et al. 2013, 2016, 2017a, b; Ajayi et al. 2014; Okpeku et al. 2016b), genetics basis of muscle formation in myo-statin genes (Sanni et al. 2018), evolution of thermotolerance of disease resistance (Okpeku et al. 2016b) and the evolutionary process leading to domestication (Zheng et al. 2020).

Genomic studies have provided evidence that supports a high level of genetic diversity but weak phylogeographic structure (low genetic differentiation between breeds) in native African goats, attributed to extensive intermixing, confirming earlier reports based on mtDNA (Awotunde et al. 2015; Tarekegn et al. 2019) and microsatellite markers (Okpeku et al. 2011a; Nguluma et al. 2018) studies. Genome-wide autosomal markers using a caprine 50K single nucleotide polymorphism (SNP) chip (Monua et al. 2020; Tarekegn et al. 2019) and being used to validate reports of goat genetics determined with mtDNA haplo-grouping. This goes to strengthen claims of genetic relatedness with Asian goats and shared ancestry with ancient domesticated goats (Zheng et al. 2020). Naderi's A haplotype is now confirmed to be the predominant type found in all regions of the continent, B has been identified in South Africa and Namibia goats, while G is reported to be limited to some East African (Kenya, Somalia, Sudan and Ethiopia) and Egyptian goats. This provision of confirmed high genetic diversity has implications for further improvement through selection within populations (Tarekegn et al. 2019).

Incorporation of genetics and genomics studies in breed improvement and breed development programmes is also becoming key in goat production systems, not only in the advanced world but also in Africa. Although a very limited number of studies exist that reported mutations in candidate genes affecting economically important traits in some African goat breeds with potential for marker-assisted selection (MAS) toward genetic improvement. These association studies, however, require further validation before implementation of MAS, given that economic traits are under the influence of many loci.

Mutations in genes affecting litter was reported implicating four SNPs, including: inhibin alpha (*INHA*) gene as g.−65C>G (5'UTR), g.2518G>A (a novel variant in exon 2), g.3041A>G (exon 3) and g.3234C>T (3'UTR) identified in Kalahari Red (KR), Red Sokoto (RS) and West African Dwarf (WAD) goats (Isa et al. 2017). MAS breeding of the WAD and KR goats suggest moderate genetic diversity at g.3041A>G locus, and does having CT genotype at g.3234 C>T locus significantly (P = 0.01) impacted larger litter size compared with CC in WAD goats, while SNP genotype at other loci were not significantly associated with litter size in goats.

In like vein, gonadotropin-releasing hormone receptor genes investigated as candidate genes for litter size in WAD (Bemji et al. 2018), Khalahari Red goats and Red Sokoto goats (Isa et al. 2019) suggest that the WAD population possesses novel SNPs (g.-29T>G in 5'UTR region), g.48G>A and g.209T>G in exon 1 that promote amino acid change from methionine to arginine. Moderate diversity and strong linkage disequilibrium was also found to exist at the SNP loci with significant association between allele G at g.-29T>G with higher mean litter size for homozygous (GG) mutant does compared with heterozygotes (GT) or homozygotes (TT), while the relationship between SNPs at the two loci detected in exon 1 and litter size was not significant. For Khalahari Red goat and Red Sokoto goat populations were also observed to possess three SNPs (g.-29T>G, g.48 G>A and g.209 T>G) detected in Red Sokoto and one (g.48 G>A) in Khalahari Red goats, all mutations occurring within 5'UTR and exon one of the gene. The g.209T>G was non-synonymous with an amino acid change from methionine to arginine at position 70 of the GnRHR polypeptide.

Milk protein polymorphism at the casein (*CSN3*) gene locus studied in Red Sokoto goats by Bemji et al. (2006) revealed three alleles: A (45.3%), B (52.3%), and M (2.3%) or variants and five phenotypes at the haemoglobin locus in the study of susceptibilities to helminth infestation. While these alleles were found similar in the studied populations, they differed in their expected proportions, suggesting differential susceptibilities to helminth infestation (Wilson 1991).

Several other polymorphisms in the prion protein gene *(PRNP)* of goat populations have been shown in North Africa, cases of Algeria cited in Fantazi et al. (2018), particularly in the more ancient African *Naine de Kabylie*, the oldest breed in North Africa. The polymorphism analysed in four main Algerian goat breeds (Naine de Kabylie, Arbia, Mzabite, Makatia) suggests that the stress-resistant allele K222 was present at a very low frequency in *Naine de Kabylie*, whereas a frequency similar to other Mediterranean countries was detected in Mzabite. The overall results showed how polymorphisms in *PRNP* of goat populations from different areas of the Mediterranean basin can differ in terms of variability and relative frequencies. Genomic information is thus changing the breeding programme in Africa from indiscriminate gambling processes to purpose-driven programmes.

5.6.3 Association of Molecular Markers with Milk Production Traits

Milk production is an essential component of livestock production. High quantity and quality of milk production is usually desired to provide nourishment for young kids and exploited for producing nourishment in meals of the keepers, excess is sold fresh or processed as dairy products sold support the keepers' economy. Genes encoding major protein and whey protein of milk are reported to be candidate genes that can be exploited in MAS to improve the milk productivity in farm animals. Ahmed and Othman (2009) genotyped four milk protein genes—CSN1S1, CSN1S2, KCN, and β-LG—in four goat breeds reared in Egypt: Baladi, Barki, Damascus, and Zaraibi. Their results revealed that the CSN1S1 gene exhibited considerable allelic diversity among these breeds, indicating genetic variation that could influence milk production traits. Three of the genotypes were homozygous (A/A (4.5%), B/B (6.8%) and D/D (2.3%)), and the other two were heterozygous (A/C (40.9%) and B/D (45.5%)). Egyptian goat breeds also carried CSN1S2 gene A, B and F alleles, while C, D, E and O alleles were not present. The frequency of homozygous and heterozygous genotypes varied significantly, and polymorphism of gene loci was also documented. Polymorphism associated with milk production parameters was reported by Eid et al. (2018).

In another study, Nowier and Ramadanl (2020) reported a significant association of G/A SNP with the lactoferrin gene, protein, solids-not-fat and total solid content of goat milk, suggesting that these could be useful markers in MAS programmes to improve goat milk composition. These results advance our understanding of the genetic basis for milk composition and would help in planning improvement, management and breeding programmes for dairy goats.

5.6.4 Association of Molecular Markers with Growth Trait

Growth hormone (GH) is the main regulator of animal growth and is encoded by the GH gene that exhibits active gene variants improving growth. The investigation of genetic polymorphisms in two functional genes (myostatin (MSTN) and prolactin (PRL)) was reported by Abdel-Aziem et al. (2018) in three goat breeds using Sanger sequence and restriction fragment length polymorphism (RFLP). In the study, the 337 bp MSTN gene profile displayed five SNPs. The MSTN-HaeIII/PCR-RFLP complex was used in genotyping goats for growth traits, revealing three different genotypes designated as AA, AB and BB, but polymorphism was limited to some breeds. The study also demonstrated polymorphism in the PRL-Eco24I/PCR-RFLP complex across all breeds, suggesting the latter as a

better marker for genetic differentiation between goat breeds relative to MSTN-HaeIII/PCR-RFLP.

Growth hormone (GH) gene that promotes goat muscles, bone formation, regulating fat content and other important traits in goats was molecularly analysed by Mahrous et al. (2018) in a study that identified three loci of GH gene (GH1, GH2 and GH6) in three goat breeds using polymerase chain reaction–restriction fragment length polymorphism (PCR-RFLP) and gene sequencing analyses. In another study, El-Halawany et al. (2017) documented SNP polymorphism in the exon-3 region of the GH gene, confirming previous study findings, and concluded that candidate growth genes could be used as a marker in the selection of goats with high growth value traits.

5.6.5 Association of Molecular Markers with Reproduction and Immune Response Trait

The association of molecular markers with reproduction and immune response traits in African goats has been studied in various research. A study that assessed the acquired immune response of different goat breeds, including South African Indigenous goats (Nguni), Saanen goats, and cross-bred goats, found that all three goat breeds exhibited an acquired immune response, but the Nguni response was significantly higher than that of the Saanen goats (Gopalraj et al. 2013). Another study on Innate Immune Response to Rift Valley Fever Virus (RVFV) found that the virus infects dendritic cells (DCs) and monocytes, inhibiting the IFN-α response and allowing rapid replication (Nfon et al. 2012). A study by Chiejina and Behnke (2011) on the Nigerian West African Dwarf goat breed found that they had a strong resistance and resilience to gastrointestinal nematode infections. The researchers believe that this trait is genetically determined and could be a breed characteristic, particularly regarding haemonchotolerance. Some other research on the impact of heat stress on goats found that heat stress results in a decrease in growth, milk and meat production and immune response in goats. However, the exact immune-regulatory mechanisms are still underutilised in goats, especially in South African goats (Visser and Snyman 2023). These researchers, associating molecular markers with reproduction and immune response traits in goats, found that various breeds exhibited different patterns of gene expression related to traits such as faecal egg count, packed cell volume, immunoglobulin A (IgA), immunoglobulin G (IgG), interleukin family genes and interferon gamma (IFN-γ) (Visser and Snyman 2023). Despite these, the general opinion is that further research is needed to better understand the underlying mechanisms and potential applications of these molecular markers in goat breeding and health management.

A study conducted by Metawi et al. (2019) analysed the polymorphism of two genes, namely growth differentiation factor 9 (GDF9) and follicle-stimulating hormone (FSHβ), in goat breeds known for high prolificacy. These genes are associated with fecundity, which implies that they can serve as molecular markers for the selection of goats with high litter size. The study suggests that these markers can be used in goat improvement programmes to enhance their breeding for high prolificacy. Several other candidate genes have been identified that are associated with reproduction traits in African goats, including fecundity and prolificacy. Some of these candidate genes include: Adenylate Cyclase 1 (ADCY1) involved in energetic metabolism, cellular mitosis and growth hormone releasing. This gene has been described in West African Dwarf goats and Cameroon goats (Salgado Pardo et al. 2022; Zonaed Siddiki et al. 2020). Heat Shock Protein 4 (HSF4), Vacuolar Protein Sorting 13A (VPS13A) and Nucleobindsin E1(NBEA) are candidate genes associated with adaptation to desert regions, dry weather and milk traits in goats (Amiri Ghanatsaman et al. 2023); these genes have been described in Asian goats raised in arid regions similar to most of sub-Saharan Africa's production environment with promising prospects in African goat relatives. Interleukin 7 (IL7), Interleukin 5 (IL5), Interleukin 23 subunit alpha (IL23A), and Leucine Rich Repeat and

Fibronectin Type III Domain Containing (5 LRFN5) (Amiri Ghanatsaman et al. 2023). These genes are associated with immune response traits, litter size traits and production function in indigenous African goats (Wang et al. 2022). These candidate genes provide insights into the genetic potential of African goats for fecundity and prolificacy. However, more research is needed to better understand the specific roles of these genes in goat reproduction and to develop strategies for improving reproductive performance in African goats.

5.6.6 Candidate Genes Associated with Immune Response/Adaptive Traits

Analysis of immune response genes to understand genetic adaptation and response to evolutionary forces in African goat evolution was reported in many studies in connection with indigenous African goat breeds. Polymorphisms of the MHC class II DRB gene in the Egyptian (Ahmed and Othman 2006; Ahmed et al. 2018) and Nigerian goats (Yakubu et al. 2017b) using an amplified fragment of 285-bp of the gene revealed various allele frequency patterns of the MHC class II DRB. Furthermore, genetic diversity of 2-decyl-4-quinazolinyl amine exon2 (DQA2 exon2) gene (Yakubu et al. 2017a; Ahmed et al. 2018) and DQB (Yakubu et al. 2013), Interleukin-2 (IL-2) gene (Yakubu et al. 2016), agouti signalling protein (ASIP) gene (Adefenwa et al. 2013) among different African goat populations from different agro-climatic areas have also been studied. These reports strengthen the knowledge that African goats possess adaptive genetic properties for disease resistance (Okpeku et al. 2016a), particularly those that are regionally prevalent where they are found. These further strengthen reported diversity in native African goats with unlimited potential for genetic manipulations for improved meat, dairy and other economic traits.

5.7 Indigenous Knowledge, Unique Features and Products from African Goats

Traditional knowledge and indigenous goat production in Africa play a crucial role in the economy, food security and livelihoods of local communities. By leveraging these resources and promoting sustainable practices, it is possible to enhance the productivity and value addition of goat production on the continent. Some of the key values include:

Meat and Milk Production: Goats raised for milk production in sub-Saharan Africa are comprised of indigenous and cross-bred breeds. Goat meat and milk are essential sources of protein for pastoralist communities in the region (Kahi and Wasike 2019).

Natural Resource Management: Traditional methods of Rwandan goat production and management involve allowing goats to graze in open areas, which contributes to sustainable land use and conservation of natural resources (Khowa et al. 2023).

Livelihood Opportunities: Goats serve as an economic safety net for pastoralist communities, providing income through the sale of animals, meat and milk products. Goat products are also used for various purposes, such as blood for food in some pastoralist communities, skins for the leather industry and manure for fertiliser (Kahi and Wasike 2019).

Cultural Significance: Goat meat and milk are traditionally accepted in some cultures within countries and are usually promoted as livelihood programmes. Urban goat production exists but is scanty, and commercial production is limited (Kahi and Wasike 2019). These products, which have strong cultural, economic and medicinal values, reflect social and economic dynamism and employ a variety of methods, with a majority of the workforce being females. Despite their roots in the African culinary tradition, these products have

evolved to play significant roles in not only the food and economy of the producers but also reflect the region and sometimes tribes from where they are made, with special reference to traditionally made butter, curd, cheese and yoghurt. Additionally, other values derived from goats in different cultures confirm their roles in improving household food security, income and sociocultural roles among rural communities in Africa (Pollott and Wilson 2009).

Community-Based Breeding Programmes: Community-based breeding programmes for improved goat production with a focus on the improvement of observable phenotypes, production and productivity have been implemented in some countries, leveraging traditional knowledge and indigenous goat production to enhance productivity and value addition (Monau et al. 2020). Generally, goat breeding is often associated with rural and pastoral agriculture, with a focus on meat and dairy production to support household needs and contribute to farmers' economy on a small scale. See Chap. 17, which addresses utilisation dimensions through the development of appropriate breeding goals and strategies.

Market Opportunities: Sheep and goats contribute to supplying markets with food and non-food products, offering export-earning and import-saving opportunities for local communities (Pollott and Wilson 2009). The manufacturing of these products employs indigenous knowledge, passed down from generation to generation (CNL 2019). Processing and preservation employ techniques that vary by regions and territories. The use of goatskin water bags or pottery in some regions confirms specificity in manufacturing, linked to traditional practices (Khoualdi 2017). For instance, salting, draining and refining of *Bouhezza* cheese are done simultaneously in a permeable goatskin water bag or 'Chekoua' with the incorporation of red chilli powder; thus, the production lasts several weeks to several months with a strong acidulous taste characterised by this cheese (Medfouni and Benidir 2018). These are some value chain products from goat rearing apart from the skin sold for money and processed into leather for bags, shoes and belts, among others. The Red Sokoto goat skin was particularly famous for making quality leather. Horns and bones from goats are have also been known to be burnt and processed into China plates and other products for household uses. Ethiopian hides and skins have a good reputation in the international market. The international leather market for its unique natural substance of fitness, cleanness, compactness of texture, producers thickness, flexibility and strength. Specifically, the goat variety around the Bati area in Ethiopia is known for its superior quality. According to Made (2017) 'Bati-genuine' is associated with the highest quality class goatskins in the world. The particular characteristics of Ethiopian bati-genuine goat skins are their thickness, high flexibility and clean inner surface, and they are known worldwide for being an excellent raw material for producing high-quality suede leather.

Dietary Contributions: Meat and milk products from small ruminants, including goats, contribute to dietary diversity and provide essential nutrients for human consumption (Pollott and Wilson 2009). Milk is perishable, so it is processed into products often determined by the traditional and cultural needs of locales.

Butter from goat milk is known as *S'men* in some parts of North Africa. It is made by churning plain goat milk, cultured milk or cream in mixers until a butter lump is formed and then cooled and separated from the buttermilk. These either contribute to household meals, are sold for money or offered as a gift.

Fermented milk products include yoghurt, *Raib* (curdled milk), and *D'han* (fermented curdled milk), obtained at the end product of curdling milk from goat and other ruminants. These are often served as dairy beverages chilled and contribute to family incomes as well.

Cheese, known variously as *Djben*, *Klila* (Hallel 2001) in Northern Africa, called *Wara* by the Yoruba-speaking tribes in Nigeria, West Africa, and other various names across the conti-

nent, is among the list of traditional milk products prepared from raw milk (Ould Abeid et al. 2013), consumed within 10 or 15 days of its preparation. There is also *Bouhazza* (Fig. 5.19), a traditional cheese, refined, soft and spicy, unmolded, and very common in the East of Algeria (Aissaoui-Zitoun et al. 2012). *Michouna* is a fresh cheese made from the milk of cows or goats or the mixture of both (Derouiche and Zidoune 2015). *Klila* is a traditional cheese, eaten fresh or dried, prepared from the milk of a cow, sheep or goat or a mixture of the three. Its empirical manufacturing process is still in force, and characterised by spontaneous fermentation of the original Flores of milk at room temperature. After clotting and draining, the product is consumed fresh or after drying for several weeks (Boubekri and Otha 1996). *Medeghissa* is a traditional Algerian cheese known to the Chaouia under its original name, *Imdeghest*. It is a melted cheese, prepared by cooking *Klila* semi-dry in the whole milk of a cow or goat, on a low heat (Khoualdi 2017).

Benefits to the Farming System Goats contribute to sustainable farming systems by consuming local feeds, utilising marginal lands and providing manure for fertiliser (Pollott and Wilson 2009).

Fig. 5.19 Original *Bouhezza* cheese from Algeria

Preservation of Local Breeds Indigenous goat production contributes to the conservation of local breeds, which are adapted to specific environments and ecological niches, providing genetic resources for future improvement and development of African goat breeds (Monau et al. 2020).

In Africa, several value chains have been identified in goat-rearing communities across the continent based on their development potential and their relevance to the targeted populations, particularly in terms of the inclusion of a large number of small enterprises and beneficiaries (Abdelfettah and Fantazi 2020), major among these are milk and dairy products, known to support significant local demands but face serious competition from imported products such as powdered milk.

5.8 Conclusion and Future Perspectives

5.8.1 Conclusion

This chapter discussed the African goat genetic resources in terms of its importance, origin, geographical distribution, introgression between and among populations, and the nature of phenotype, molecular and genomic characteristics.

Archaeological and molecular studies suggest the Middle East and the Asian region as centres of domestication for goats. Their dispersal was mainly through human migration and trade, leading to the creation of sub-species based on five key ecological regions of Africa. Through localisation, adaptation to farming systems, climate and human needs, and introgression, a total of 289 goat breeds currently exist in Africa. Eastern and Southern Africa dominate with 180 breeds, while Western, Northern and Central Africa share the rest.

Morphological and genomic studies show that Africa has the richest diversity of goats, each locally adapted to specific locations and niches, hence described as local breeds. Apart from these, a few breeds have been developed into

composites and have been used to improve local breeds in other countries, hence termed exotic breeds, led by Boer and Angora goat breeds. Saanen, Togenberg and Alpine have been introduced in a few countries to promote goat milk production. Within other countries such as South Africa, Mozambique, Tanzania, Togo, Algeria and Morocco, some attempts have been made to develop locally adapted breeds.

Regardless of region and ecological zones, African goats are commonly utilised for meat, a source of income, and for sociocultural roles among the majority of rural communities in Africa. Goat milk is traditionally accepted in some cultures within countries and usually promoted as livelihood programmes. Urban goat production exists but is scanty and so is commercial production. In commercial settings and research and academic institutions, goat meat and milk values chains produce biltong and goat cheese, respectively.

African goats also share similarities in production and reproductive traits, with local breeds maturing at between 30 and 40 kg, while exotic breeds reach up to 60 kg live weights. Twining is common. Trait variations exist within and between populations, meaning there is a high likelihood of improving African goats using crossing and line breeding strategies.

Being a poor man's cow, African goat offers a better livelihood and commercialisation tool that can enhance the livelihood and equity of wealth distribution among the majority of rural communities in Africa. Their commonality in roles provides a clue that similar strategies can be employed to improve their productivity and value addition and similarly drive the commercialisation of African goat.

5.8.2 Future Perspectives

Indigenous goats of Africa's unique breeds have great potential to strengthen agriculture, tradition, culture and the economic structure of the communities where they exist. Despite their valuable features and products, the majority of these breeds are still underutilised and understudied. More so, available diversity makes them promising genetic resources for developing improved African goat breeds that are valuable locally and for international exports.

To fully utilise these genetic resources, it is crucial to prioritise and intensify research on the genetic characterisation of indigenous goat breeds to understand their genetic architecture, particularly at the molecular level. This will enable the design of effective breeding programmes for improvement.

Prioritising research on the genetic characterisation of indigenous goat breeds and promoting public-private partnerships can help unlock the potential of these unique breeds and contribute to the sustainable development of African communities. To support research, cushion breeding and provide an enabling environment for breeding, public-private partnerships are recommended. Indigenous livestock breeds are valuable assets of the communities where they are found. As such, future interventions for improvement should be carried out in partnership with locals who will be the owners and end-users of future improved products.

6 African Sheep Genetic Resources, Diversity and Unique Features

Martha N. Bemji, Semir B. S. Gaouar, Abdelkader Ameur Ameur, Fatima Z. Belharfi, Isidore Houaga, and Anne W. T. Muigai

Abstract

Africa is host to over 363 breeds of sheep, the majority of which have not been characterised. The total sheep population is 27.1% of the global sheep genetic resources, placing Africa in the second position worldwide. This Chapter introduces indigenous African sheep breeds, their origins, their history of domestication, dispersion in Africa and their role on the continent (Sects. 6.3 and 6.4), thus providing a broad coverage of African sheep, using a framework that could trace the roots of current breed groups. Section 6.5 is devoted to a discussion on different sheep breeds of Africa, which are classified into two major classes based on tail morphology (thin-tailed and fat-tailed or fat-rumped) and further subdivided into seven subtypes (thin-tailed hair sheep, thin-tailed coarse wool sheep, fat-tailed hair sheep, fat-tailed coarse wool sheep, fat-rumped hair sheep, introduced breeds and developed or composite sheep breeds). For each breed, the chapter summarises the origin, distribution and classification, physical characteristics, including some breed photos, adaptive and special genetic characteristics, typical production systems and production characteristics. The depth of discussion is dif-

ferent between breeds due to the differential availability of data or information. Sections 6.6, 6.7, 6.8, 6.9 and 6.10 further appraised the current status of sheep diversity in Africa, conservation of sheep genetic resources, sheep breeding goals and strategies for sustainable sheep genetic improvement, responses of existing sheep to selection, structure and organisation of the sheep sector in Africa and sheep production capacity in terms of meat, milk, wool and skin. In Sects. 6.11 and 6.12, the chapter concludes with an overview of challenges to sustainable genetic improvement in the sheep industry and future prospects.

6.1 Introduction

Africa is endowed with enormous sheep genetic resources, which is the second largest mammalian species, with over 363 breeds, most of them originating from Southern Africa (109), followed by East Africa (99), North Africa (65), West Africa (62) and Central Africa (28) (AU-IBAR 2019). However, only a limited number of the breeds have been characterised. As indicated in Table 6.1, this huge genetic resource positions the continent as the second largest producer in the world in terms of percentage of live animals (27.1%), meat (mutton) (18.2%), fresh skin (16.2%) and edible offal (21.2%), while ranking third in total fresh milk production valued at 2,040,376 tonnes (21.9%) (FAOSTATS 2019). The total African sheep genetic resources for the year 2019 were estimated at 407,652,676. As outlined in Chap. 2, with more current data, West Africa ranks highest in sheep production, followed by North Africa, East Africa and Central Africa, while the least production comes from Southern Africa, corroborating the earlier trend between 2018 and 2019 (Table 6.2).

In the most vulnerable arid and semi-arid zones in sub-Saharan Africa (see Chap. 2 for a detailed description of the main agro-ecological zones in Africa), sheep are among the most frequently owned animals (Seo 2021) that perform numerous roles in many smallholder farm families who depend on sheep production for their livelihood. Almost two-thirds of rural households keep livestock in sub-Saharan Africa (FAO 2014). The minority of livestock keepers in Africa, who are pastoralists, migratory or sedentary, or agro-pastoralists, keep relatively large herds, while the majority keep an average of 5.5 animals, with half of these also keeping other livestock species such as cattle or goats and a few sheep (FAO 2014). Studies have shown that sheep farming offers several advantages over goat farming. The average annual rates of return on capital for the production of the dwarf sheep and goats in Southwest Nigeria was 55% for sheep compared to a lower estimate of 34% for goats (Upton 1985), with a sensitivity analysis further showing that at high levels of mortality, the risk of loss appeared lower for sheep.

Outstanding advantages that make the sheep industry pivotal in reducing poverty, which is endemic in Africa, include the sheep products, including meat, milk, skins, fibre, horn and offal, by-products such as manure used as fertiliser,

dung used as fuel and for biogas production. The indirect benefits of keeping sheep include their use for weed control and for intangible benefits such as their use as a store for capital, income generation, reduction of risk from crop failure, fulfilling social, cultural and religious obligations, providing status or prestige and use in sport, culture and recreation (Pollott and Wilson 2009). Growth in meat demand in sub-Saharan Africa between 2013 and 2015 indicates that the sheep industry grew impressively, and sheep meat consumption was sustained at a similar rate, with imports accounting for a very small share of additional consumption compared to meat from other livestock species (OECD and FAO 2016). Consumption preferences reflected cultural and religious preferences. Growth was significantly faster in Eastern Africa compared with other regions in sub-Saharan Africa, where sheep are extensively raised on pasture. This trend has been maintained, being supported by more current statistics (Wilson 1991). Major producing countries are Sudan and Ethiopia (East Africa), Nigeria, Mali and Niger (West Africa), Algeria, Morocco, Tunisia and Egypt (North Africa), South Africa (Southern Africa) and Chad (Central Africa).

The two major classes of sheep, recognised as thin-tailed and fat-tailed, are further subdivided into four types (Wilson 1991) based on tail morphology and coat type. They include thin-tailed with hair, thin-tailed with wool, fat-tailed and fat-rumped. As indicated in a review by Muigai and Hanotte (2013), fat-tailed sheep constitute the majority in most parts of North Africa (from Egypt to Tunisia) and in Eastern and Southern Africa (from Eritrea to South Africa). Thin-tailed sheep are mainly found in North Africa (Morocco to Egypt), Sudan and West Africa (Senegal to Nigeria). Two subtypes of thin-tailed sheep (the African long-legged and the tropical dwarf sheep) have been identified. The former is widely distributed in the arid and semi-arid zones of the Sahel and West Africa, while the latter is mainly found in the sub-humid and humid zones of West and Central Africa.

Diversity studies with molecular markers, for example, microsatellites (Gaouar 2002; Gizaw et al. 2007; Gaouar et al. 2016; Ameur Ameur et al. 2018; Nigussie et al. 2020), mitochondrial DNA (Agaviezor et al. 2012; Brahi et al. 2015; Ghernouti et al. 2017) and genome-wide SNP chip (Gaouar et al. 2017; Edea et al. 2017) analyses revealed high levels of genetic admixture between African breeds of sheep, particularly among populations within the same geographic area, leading to higher within-breed than between-breed genetic diversity. This could be largely attributed to uncontrolled breeding, which often characterises most production systems.

The following topics will be discussed in this Chapter: (1) a brief history of the introduction and dispersal of African sheep, (2) the importance and uses of sheep genetic resources in Africa, (3) phenotypic and genetic characterisation of sheep breeds with emphasis on unique attributes of adaptation and productivity, (4) the current status of sheep diversity and conservation, (5) responses of existing sheep breeds to selection and their limitations, (6) sheep breeding goals and strategies and (7) structures and organisations of the sheep sector in Africa.

6.2 Structures and Organisation of the Sheep Sector in Africa

African sheep production is a subset of the larger livestock production systems that have been comprehensively discussed in Chap. 2 (Seré and Steinfeld 1996; FAO 2007). In Africa, however,

there is no single classification that can be used to map the livestock production systems across the continent (Herrero et al. 2010; Robinson et al. 2014). Sheep production largely depends on rainfed pastures that are dependent on seasonal rainfall patterns and existing environmental conditions. As a result of this, the production of sheep in Africa can broadly be described as follows: (i) agropastoral and pastoral systems, (ii) mixed crop-livestock systems and (iii) landless systems, which have been discussed in Chap. 2.

The 'Livestock Revolution' discourse (Delgado et al. 1999), which points to growth in demand for livestock and their products (meat and milk) due to rising incomes and urbanisation in developing countries including Africa, has so far perhaps largely been confined to emerging countries, and it is difficult to predict a comparable explosion in the consumption of animal products in sub-Saharan Africa in the coming decades. No doubt increases in human population, urbanisation and changes in consumption patterns will result in changes to consumption of livestock and livestock products, with the FAO predicting a doubling of per capita meat consumption in Africa by 2050 (from 11 to 22 kg/year/capita). There are also indications that Africa, over time, will become a net importer of meat and animal products, with imports accounting for between 12% and 15% of the meat and meat products being consumed on the continent.

6.3 Brief History of Domestication, Introduction and Dispersion of Sheep in Africa

6.3.1 The Domestication of Sheep

The first animal to be domesticated was the dog (Clutton-Brock 1997) followed by sheep and goats, which are the earliest bovids to have been domesticated around 10,500 BP (Zeder 2011). Present-day sheep, *Ovis aries*, evolved in Eurasia (Uerpmann 1987; Ryder 1983) in the early Pleistocene period around 2.5 million years ago (Ryder 1983) from its wild progenitor, the *Ovis orientalis*, which was confined to the Taurus/Zagros Arc region (Zeder 2017). Domestication of sheep, goats, cattle, yak, water buffalo and perhaps pigs was not a one-time event but rather a process that began with the animal first being hunted by man in regions that were remote from human settlements, followed by their being managed as game and finally to their being fully domesticated (Zeder 2011; Larson and Burger 2013). Domestication involved bringing the animals into close proximity with humans, which led to their being managed and bred extensively by man (Zeder 2011; Larson and Burger 2013).

Mitochondrial DNA sequence analysis is a molecular tool that can be used to infer the origin of species and has been widely used to reconstruct the patterns of domestication (Groeneveld et al. 2010). It has been revealed that at least three distinct lineages of the wild sheep, *Ovis orientalis*, were involved in the domestication process (Pedrosa et al. 2005), probably in the eastern Taurus and northwestern Zagros region, which has also been associated with goat domestication (Demirci et al. 2013). These lineages do not, however, provide evidence of multiple and independent domestication processes, but instead show mitochondrial introgression was a result of continuous admixture between wild and initial domesticated animals outside the domestication regions (Larson and Burger 2013). This mouflon–domestic sheep cross-breeding is thought to have been either naturally occurring and/or human-mediated (Lauvergne et al. 1977; Schröder et al. 2016; Barbato et al. 2017). Evidence for the matings between feral and domestic sheep has been provided by microsatellite marker analysis (Schröder et al. 2016; Lorenzini et al. 2011; Guerrini et al. 2015).

6.3.2 Dispersal of Sheep Out of Their Centre of Domestication into Anatolia and Europe

While man was domesticating animals, he was also domesticating plants, resulting in the expansion of human populations and the development of communities that were engaged in cultivation and husbandry of domesticates (Bocquet-Appel

and Bar-Yosef 2008). These populations then migrated away from the centres of domestication (eastern Taurus and northwestern Zagros region), taking their domesticated animal and plant species with them. Managed sheep that were in various stages of domestication appeared in the Zagros around ca. 9000 (Zeder 2008) and in the Levant slightly before this time (Horwitz and Ducos 1998). The earliest evidence of sheep populations outside the Levant came from Cyprus, dating to ca. 10,500 BP, reaching the other islands of Corsica and Cyprus by ca. 6000–7000 (Zilhão 2001; Vigne et al. 2014) having been transported across the eastern Mediterranean in boats. Morphologically wild but managed sheep appeared in Central Anatolia in ca. 10,000. There is debate on whether these sheep were the result of independent domestication of local wild sheep or whether they were managed sheep dispersed from the east (Buitenhuis 1997; Vigne et al. 1999). Nevertheless, there is evidence of managed caprines by early animal keepers as early as ca. 10,400–10,100 (Stiner et al. 2014). By 9500 BP, there were sheep in south-central Anatolia (Russell et al. 2005) ,where sheep were 2–3 times more prevalent than goat (Çakirlar 2012a, b). From Anatolia, domestic livestock, including sheep, was dispersed into Europe following two pathways, the first was across the Mediterranean Basin, beginning in Cyprus (10,500 ka) and moving onto Crete (9000 BP (Efstratiou et al. 2004)) and both Corsica and Sardinia (7700 BP), and the other was dubbed the 'Danubian dispersal', through the river valleys of south-eastern and central Europe and beyond, with sheep being reported in southern Istria at the head of the Adriatic in 7700 BP, southern Italy 8000 BP (Skeates 2003), southern France 7700 BP (La Guilaine 2006; Guilaine et al. 2007; Rowley-Conwy 2013), Iberian Peninsula (7700–7500 BP) and Portugal (7400–7300 BP) (Zilhão 2001; Zilhão 2003).

6.3.3 The Dispersal of Sheep into Africa

Dispersal of sheep into Africa is not as well documented as done for the other continents. This is partly due to the initial focus of early African archaeology on early and modern humans and their dispersal, but also because the environmental conditions experienced in Africa (such as adverse soil chemistry) made the preservation of faunal remains more difficult. Although the case for an African centre of domestication for cattle has been made (Gautier 1987; Wendorf and Schild 1998; Muzzolini 2000), the lack of strong genetic evidence to support this has made it likely that all domestic livestock were introduced into Africa.

There are two possible routes for the introduction of domestic sheep into Africa. The first follows the southerly migration of sheep through the Negev of southern Palestine, across the Sinai Peninsula to the Red Sea Coast (Close and Wendorf 1992; Garcea 2004). Evidence for this route is provided by sheep remains recovered from the Nile Delta, the eastern Sahara and the Red Sea Hills, dated between 7000 and 7500 BP (Gautier 1987; Close 1992; Vermeersch et al. 1994). These are the earliest remains of sheep in Africa, and they are likely to have originated from the Sinai Peninsula, where sheep finds are dated *c.* 7000 BP (Oren 1979).

The second dispersal route of sheep into Africa is across the Mediterranean Basin, which possibly led to the introduction of sheep into the Libyan Cyrenaica, northern Algeria and Mediterranean Morocco between 7000 and 6500 BP (Higgs 1967; Gilman 1975; Roubert and La Carter 1984; Klein and Scot 1986; Pereira et al. 2006). The livestock keepers seem to have settled along the northern African Mediterranean coastline but eventually migrated southwards, settling in the central Nile Valley (6000 BP) and the more hospitable regions within the Sahara (Close 1992).

Livestock herding spread quickly but incompletely across the Sahara, with herders migrating southwards and eventually westwards into West Africa as climatic conditions in the Sahara deteriorated during the sixth millennium BP (Drake et al. 2011), reaching western Niger and the West African Sahel at approximately 6000 BP and 5400 BP, respectively (MacDonald and MacDonald 2000). At approximately the same period herders following the River Nile migrated

south from the Nile Delta to better-watered regions such as the Khartoum Nile in southern Sudan (Gautier 1987; Clark 1976; Peters 1986), reaching the Lake Turkana Basin between 4500 and 3500 BP (MacDonald and MacDonald 2000; Barthelme 1985), thus introducing sheep into East Africa. In addition to this, the direct introduction of sheep into East Africa could also have occurred via trade routes that occurred between the Arabian Peninsula and present-day Eritrea (Marshall 2000; Boivin and Fuller 2009). The picture of the dispersal of sheep into Central Africa has not clearly emerged, partly due to the low number of excavations occurring in this region, but also the poor state of faunal finds. Here, the earliest dates for caprines occur at approximately 1800–1000 BP (Van Neer 2000).

The sheep of southern Africa came from further north, with different routes and chronologies being proposed (Elphick 1985; Bousman 1998; Russell 2004). When the first Europeans arrived on the southwestern coast of southern Africa, they found indigenous Khoe speakers with sheep (Elphick 1985; Stow 1905; Cooke 1965). Questions on the route these sheep took and the identity of their keepers have been seriously debated. New evidence is pointing to the fact that the earliest sheep arrived in southern Africa, with cattle, approximately 2000 years ago via two separate routes (Sadr 2015). One route located in the extreme western part of the continent involved hunter-gatherers migrating southwards along the Atlantic seaboard, reaching the most southern tip of Africa (Sadr 2015). Around the same time, a smaller group of hunter-gatherers, with sheep and cattle, reached the middle Limpopo River Basin, migrated westwards into the Kalahari Drainage Basin as far as Lake Ngami and migrated further to the north and west of Lake Ngami (Sadr 2015). Genetic evidence for the southerly migration of pastoralists from the East African nation of Tanzania into southern Africa has been reported (Henn et al. 2008, 2011). These early pastoralists who came from East Africa are believed to be Khoe-Kwadi speakers. The introduction of livestock into the South African region is thought to be the result of small-scale infiltrations of pastoralists with their animals (Sadr 2015).

6.4 Importance and Use of Sheep Genetic Resources in Africa

6.4.1 Role in Agriculture

The indigenous sheep of Africa play various roles in African communities and form an integral part of their day-to-day activities. Sheep and sheep products are direct contributors to food and nutrition security, providing meat, milk and other products (Table 6.1). Sheep and other livestock species are direct contributors to the agricultural economies of African countries, contributing up to 40% to the GDP, excluding the contributions made by draught power and manure (Winrock International 1992). For example, in 2009, the net annual sheep offtake rate reported in Uganda, South Sudan and Sudan was USD 10 million, USD 1.5 million and USD 4.6 million, respectively (Behnke and Osman 2012; Kosgey et al. 2008). The sales of fresh sheep milk were also reported to generate USD 810,000 and USD 2.5 million in South Sudan and Sudan, respectively, in the year 2009 (Behnke and Osman 2012). Incomes, especially those from exports, are also generated from the sales of live animals, leather and leather products.

Sheep are an important resource for African women and children who, in many regions, are their owners and managers. Studies conducted in Kenya, Tanzania and Mozambique demonstrated that after chickens, sheep were the most important species owned, followed by goats, although the proportion of animals owned was generally lower than what was owned by men (Njuki and Mburu 2013).

Few African farmers have access to commercial fertilisers and the few who do find the cost prohibitive. Manure and urine from indigenous sheep are essential components of African agricultural production. In addition to this, dried dung is used as a source of fuel. However, the exact contribution of manure from sheep and other livestock is not known.

The pastoralists who keep the majority of the sheep in Africa inhabit some of the most fragile ecosystems in the world that continuously face

challenges of recurrent droughts and threats of desertification. However, these pastoralists have inhabited these lands for generations and thus know how to manage these resources sustainably by migrating out of ecosystems when the water and grass resources diminish and returning when they have had a chance to be replenished. Their utilisation of these lands that would otherwise not be utilised is an important benefit and contribution. The pastoralists contribute significantly to the economies of these countries by providing food to their families and the surrounding villages and towns. Unfortunately, this important contribution by pastoralists is seldom recognised by governments and administrators (Blench 2001), especially because of the concerns that have been raised on the role that overgrazing plays in environmental degradation (Foley et al. 2005).

6.4.2 Sociocultural Role of Sheep Across Africa

The primary reason for keeping sheep in Africa is for sustenance and for providing an income at the household level. However, sheep also perform important cultural roles and are used as part of African expression at different ceremonies, including weddings, funerals and day-to-day living. Sheep are important in the day-to-day lives of their owners, conferring status and power, and are used in the development and nurturing of relationships between members of a community. Many African cultures sacrifice sheep and other livestock as part of their religious or customary practices.

6.5 Sheep Breeds of Africa and Their Adaptive Features

There are an estimated 1.3 billion head of sheep in the world, one-third of these (approximately 418 million head) are found in Africa (FAOSTATS 2021). Illustrations of sheep from ancient Egypt suggest that the sheep present during the pre-dynastic and early dynastic periods were thin-tailed. These sheep are depicted with a straight head profile, long, thin legs, a long, thin tail that reached the hocks and were often black, white or pied. However, they were later replaced with fat-tailed sheep. Sheep illustrations after the 12th Dynasty in ancient Egypt show fat-tailed sheep (Ryder 1983). It is considered that these sheep easily replaced the thin-tailed breeds because of their coarse wool and fat tails, which were a valuable storage organ to pastoralists (Ryder 1983).

Thin-tailed sheep of large size are found in the northern dry tropics, while small or dwarf sheep are in humid areas of west to central Africa. Fat-tailed sheep are predominant in east Africa, extending to Mozambique, while fat-rumped sheep are most common in traditional systems in north-east Africa, but have also spread to commercial systems in Zimbabwe and other countries within the southern region.

Nine subtypes of sheep, as presented in Table 6.3, can be distinguished in sub-Saharan Africa (Gatenby 2006) comprising a variety of breeds and a large number of varieties or strains. Although there is no consistency in the classification of sheep breeds identified by different authors in Table 6.3 (Wilson 1991; Gatenby 2006; DAGRIS 2007), five of the types, namely, the thin-tailed hair, thin-tailed coarse wool, fat-tailed hair, fat-tailed coarse wool and fat-rumped hair sheep, are indigenous to Africa. Other classes include exotic or introduced sheep breeds and developed breeds through cross-breeding for specific purposes, which will all be considered in subsequent discussions.

6.5.1 Thin-Tailed Hair Sheep

The present-day thin-tailed hair sheep of Africa are mainly found in West Africa, extending from Sénégal to Nigeria, northwards towards Morocco and eastwards to Sudan. These sheep closely resemble the sheep that were found in ancient Egypt and are considered the most primitive on the continent (Ryder 1983). They were the first to migrate into Africa from the centre of domestication through the Isthmus of Suez and diffused

Table 6.3 Classes of sheep breeds in Africa

S/N	Breed type/breed	Synonym(s)	Location
1	**Thin-tailed hair sheep**		
(i)	***Dwarf type***		
	West African Dwarf	Djallonké, Fouta Djallon, Forest sheep, Mouton Guinéen, Mouton Nain d'Afrique occidentale, Kumasi, Ghana Dwarf, Nigerian Dwarf, West African Maned, Blackbelly, Mayo-Kebbi, Kirdi (southern Chad/northern Cameroon) Cameroon Dwarf and Congo Dwarf	Southern Senegal to Chad, Cameroon, Gabon and Congo
	South Sudanese	Sudanese Maned, Southern Sudan, Nilotic, Nuba Maned, Mongalla	Southern Sudan
(ii)	***African Long-legged type***		
	Balami	Fulani, Borno white	Senegal to Cameroon
	Uda	Oudah; Peul; Bali-Bali; Zaghawa (Chad); Bororo and Fellata (Western Sudan)	Senegal to Cameroon, central Chad to western Sudan
	Yankasa	White Fulani,Y'ankasa, Hausa	Senegal to Cameroon
	D'man	D'men, Damana, Demnan, Demmane, Demane and Tafilalet	South-eastern Morocco, southwestern Algeria and southern Tunisia
	Ouled Djellal	Arab white sheep	Algeria
	Ara Ara		Central and South-central Niger
	Peul-Peul	Fulani (English), Foulbé	Central Senegal
	Sudan Desert Sheep	Arab, Northern Sudanese, Desert Sudanese, Ashgur, Shugor, Butana, Beja, Drashiani, Dubasi, Gash, Kababish, Watish, Baqqara, Barka (Shukria), Hamale	Northern Sudan, Western Eritrea, Chad
	Maure, Black Maure	Moor, Mauritania, Arab	Mauritania (Hodh region), northern Mali, western Niger flood zone, northern Senegal
	Touareg	Grand Targui (Ara-Ara, Argooradji), Petit Targui, Tuareg	North-east Mali, Niger, Timbuctoo, south Algeria
	Angola Long-Legged	Goitred, Zenu	Northern and Eastern Angola
	Baluba		Katanga, Zaire
	Dongola (Coarse wool?)		Northern Sudan
	Zaire Long-legged, Congo Long-legged Baluba	Congo Long-legged, Sudanese	North-east Zaire
	Touabire	Landoum, White Maure, White Arab, short hair Maure	
	Angola Maned	Coquo

Wilson (1991), Gatenby (2006), DAGRIS (2007)

overland into north and west Africa (Muigai and Hanotte 2013).

They are divided into two subtypes, the tropical dwarf and the African long-legged (Rege et al. 1996). The tropical dwarf sheep are mainly found in sub-humid and humid zones of west Africa, Sudan and South Sudan (Table 6.3). They are characterised by a straight nose and erect ears. These sheep are small in size, with an approximate height of 40–60 cm and weighing an average of 20 kg. The African long-legged sub-type is kept in large migratory flocks mainly in dry, arid and semi-arid areas that range from Mauritania on the west coast of Africa extending to Mali, Niger, Chad and Sudan in the east (Gatenby 2006) (Table 6.3). These sheep are characterised by a convex nose, pendulous ears and exceptionally long legs that give them a height of over 60 cm, which is an adaptation to the dry environments and the pastoralist lifestyle of their owners (Wilson 1991; Ryder 1983). All breeds classified in this group have a hairy coat, except the Macina breed, which has a coarse wool coat. The litter size is small, where twins are not common and triplets are very rare. The long-legged sheep breeds of Africa, namely, the Fulani, Maure and Tuareg, are named after the pastoralists who are their owners and managers. In West Africa, the sheep of the nomadic Fulani, also known in French as Peul or Foulbe include Balami (Bornu), Uda, Yankasa, Samburu, Torunke and some other strains (Gatenby 2006). Different breeds of thin-tailed hair sheep will be appraised in subsequent sections.

6.5.1.1 West African Dwarf and Cameroon Blackbelly Sheep

West African Dwarf Sheep

Distribution and Classification: The West African Dwarf (WAD) Sheep (Fig. 6.1) is also known as Djallonké, Fouta Djallon, Forest sheep, Mouton Guinéen, Mouton Nain d'Afrique occidentale, Kumasi, Ghana Dwarf, Nigerian Dwarf, West African Maned, Blackbelly, Mayo-Kebbi, Kirdi (southern Chad/northern Cameroon), Cameroon Dwarf and Congo Dwarf (Wilson 1991; DAGRIS 2007). With respect to subtypes, the Kirdi (Kirdimi or Massa) in northern Cameroon and southwest Chad is a black variant of WAD sheep, also known as Poulfouli in the far north of Cameroon and several other local or regional names in West Africa from southern Senegal to Chad, Cameroon, Gabon and Congo.

Physical Characteristics: The WAD sheep (Fig. 6.1) is a very small and compact sheep breed of 40–60 cm at withers (Wilson 1991). Apart from the Kirdi, which has been selected for a black coat, other members of the breed have varied coat colours ranging from brown, white, black or spotted black or brown on a white coat (Adu and Ngere 1979; Bemji et al. 2012). Other characteristics as reviewed by Wilson (1991) include short and stiff hair (males may have a heavy mane and apron of long hair), well-developed horns in males which are wide at the base, curving backwards, outwards and forward, fine and short horns when present in females, a strong and broad head with a flat forehead (profile slightly bulging in males), a wide muzzle and less prominent eyes, short ears (10 cm), narrow and pendent or semi-pendent, neck is long and chest is fairly deep with chest circumference 20% greater than the withers' height.

Adaptive and Special Genetic Characteristics: The WAD sheep is a very strong and hardy breed that has been described as being trypanotolerant and resistant to roundworms (Gatenby 2006). The breed is adapted to the humid rain forest

Fig. 6.1 West African Dwarf Ram at Federal University of Agriculture, Abeokuta, Nigeria. (Photo: Ismaila Muritala)

zone of Central and West Africa, also extending into the derived savanna and sub-humid regions.

Typical Production Systems and Production Characteristics: The WAD sheep is an exclusive meat breed owned by many ethnic groups in various agricultural systems, including traditional smallholder, migratory (nomadic and transhuman) and modern (ranching and finishing units) (Wilson 1991; Njuki and Mburu 2013). Estimates for reproductive traits reviewed by Wilson in 1991 (Wilson 1991) include: A*ge at first oestrus:* 250 days (206–322), *oestrus cycle:* 17.4 days (16–19) with heat lasting for 36 h (12–60 h), *gestation length*: 148.1–150.2 days on station in Côte d'Ivoire, age at first lambing ranged from 350 to 572 days depending on management system, *lambing interval*: 244–663 days depending on management system and parity of ewe, 241–275 days under controlled breeding systems, multiple births are numerous, twins common, triplets rarer with average litter size ranging from 1.15 to 1.5 depending on environmental conditions, f*ertility* (number of females giving birth/females mated): 90–96%, *fecundity (*lambs/100 ewes/year): 221% for WAD and 231% for Kirdi (north Cameroon), b*irth weight:* 1.2–2.5 kg, w*eight for age:* 1 month–4.7 kg, 3 months–9.6 kg, 12 months–18.0 kg, adult weight: male 25–30 kg, female 20–25 kg, *dressing percentage:* 43.0% at 20.2 kg live weight (Cameroon), 43.7% at 19.2 kg (Nigeria), *lactation length:* 117 days in Mali; *lactation yield*: 87 kg in Mali for supplemented ewes; maximum of 810 g/d and 1200 g/d with lactation yield of 57.4 ± 16.60 kg and 86.4 ± 29.21 kg, respectively for single and twin bearing ewes in Togo, *milk composition:* dry matter 16.5%, fat 6.0%, ash 0.8% and protein 5.4%. Heritabilities of 0.19 were estimated for age at first conception, 0.46 (dam-daughter pairs) for lambing interval and 0.26 for litter size in Cameroon. For repeatability, inter- and intra-dam variances of 0.11 for lambing interval were obtained in Senegal; estimates for weights (intra- and inter-ewe variances) were respectively 0.22 ± 0.07, 0.18 ± 0.07 and 0.24 ± 0.08 at birth, 60 and 120 days for lambs, while 0.57 ± 0.05 was estimated for ewe post-partum weight. Phenotypic correlations between ewe weight and lamb weight at birth, 60 and 120 days were, respectively, 0.20, 0.38 and 0.39.

Cameroon Blackbelly Sheep

Distribution and Classification: The Cameroon Blackbelly sheep (Fig. 6.2) is also known as 'Cameroon' or 'Cameroon Dwarf'. It is a sheep breed in Cameroon classified under the West African Dwarf group of breeds. The sheep was initially bred in West Africa for meat production but has also been domesticated in Europe, where they are used as grazers or raised as companion animals because they do not have to be shaved (https://rainwaterrunoff.com/the-cameroon-sheep-breed/). Current investigation on genetic diversity indicates that the Cameroon Blackbelly sheep are genetically distinct from other African sheep populations and are associated with a single ancestry (Wiener et al. 2022). Genes found in genomic regions of low diversity suggest biological functions that could be under strong selection, which include immune function, fertility and pigmentation.

Physical characteristics: The Blackbelly sheep has a height at withers estimated at 60–70 cm. The coat colour is brown with a black belly and black markings on the head and legs (Fig. 6.2). It has a hair coat and, in winter, grows a fine undercoat which it sheds in springtime. The females are polled, while the males have spiral horns (Fig. 6.2), a mane and a throat ruff (Rain

Fig. 6.2 Cameroon Blackbelly Ewe. (Photo: Julius Félix Meutchieye)

Water Run Off 2021) (https://rainwaterrunoff.com/the-cameroon-sheep-breed/).

Adaptive and Special Genetic Characteristics: The Cameroon Dwarf is a hardy sheep with characteristics similar to the WAD sheep.

Typical Production Systems and Production Characteristics: The Blackbelly sheep are mostly grazers. They have high prolificacy, with lambing occurring three times in 2 years, and are also noted for early maturity. Twins or triplets are common with commercial sheep breeds, but ewes can only cope with twins as the number of teats is limited to two. The gestation period is 147–50 days, weaning (3–5 months), mature live weight (30–40 Kg) and life span (12–16 years) (Njwe and Manjeli 1992). Range for average daily milk yield estimated by the indirect method of weighing lambs before and after suckling during a period of 12 weeks was 0.31–0.50 kg for ewes suckling single lambs, and maximum weekly milk yield was 3.52 kg at the 4th week of lactation, after which production declined (Njwe and Manjeli 1992) (Fig. 6.3).

Fig. 6.3 Cameroon Blackbelly Ram. (Photo: Julius Félix Meutchieye)

6.5.1.2 African Long-Legged Sheep

Balami

Distribution and Classification: The Balami sheep (Fig. 6.4) is also known as Bornu white, Bornu being the location in northeastern Nigeria where the breed is predominant. It is part of the West African Sahel (long-legged group). For s*ubtypes or races,* Balami is considered to be the same as the 'Bouli' or white Uda variety in Niger (Wilson 1991).

Physical Characteristics: Balami is a large sheep breed with a white and hairy coat and a distinct convex head with a dull depression (Fig. 6.4) (Adu and Ngere 1979). It has a dewlap-like fold of skin and a white mane, the ear is large and droopy, and the tail is thin and long. Horns are present in rams, while ewes are polled.

Adaptive Characteristics: The breed is long-legged, hardy and well-adapted to forage within the semi-arid and drier sub-humid ecological zone.

Typical Production System and Production Characteristics: The main management system for Balami is agropastoral. The breed is heavier than Uda sheep, fast-growing and can attain 18 kg weaning weight in 12 weeks. Yearling weights of 35–40 kg for ewes and 45–60 kg for rams were reported (Adu and Ngere 1979). The mean litter size increased from 1.02 at first parity

Fig. 6.4 Balami Ewes at National Animal Production Research Institute, Ahmadu Bello University, Zaria, Nigeria. (Photo: Julius C. Amabo)

to 1.6 at 54 months old, and birth weights were estimated at 3.5 kg for singles and 3.1 kg for twins (Adu and Ngere 1979; Buvanendran and Adu 2021). Estimated daily average gains for single males were reported at 142 g (101–190) (DAGRIS 2007), twins at 108 g (67–167), single females at 137 g (76–198 g) and 103 g (69–133 g) for twins at Katsina in Nigeria. The first lambing was at 18 months old and subsequent lambings at approximately 9-month intervals, with peak lambing taking place during the rainy season. Ewes lambing in the wet season had a shorter lambing interval by 50 days than ewes that lambed in the dry season. Lamb mortality to 10 weeks old was 43%, with lower survival rates for twin lambs, wet season-born lambs and lambs from primiparous ewes. Repeatabilities of lambing interval, litter size, birth and 10-week weight were 0.091, 0.087, 0.052 and 0.273, respectively.

Uda Sheep

Origin, Distribution and Classification: The Uda (Fig. 6.5) is the most numerous of the Fulani sheep (Gatenby 2006). They are alternatively known as Oudah, Peul, Bali-Bali, Zaghawa (Chad), Bororo and Fellata (Western Sudan). They originated as part of the West African Sahel (long-legged group). In Niger, the pied or Oudah bicolour and white or Bouli are considered colour variants. In Nigeria, the white variety is known as Balami and has been given a full breed status. In Chad and Northern Cameroon, the pied variety is known as Foulbé, while the white variety is known as Waïla. The Bali-Bali is occasionally seen as a separate type and is not considered a synonym in Niger. The Uda breed occurs throughout the Sahelo-Sudan vegetation zone of Nigeria (Adu and Ngere 1979), Southern Niger, Central Chad to Western Sudan and Cameroon (Wilson 1991).

Fig. 6.5 Uda Ewes at National Animal Production Research Institute, Ahmadu Bello University, Zaria, Nigeria. (Photo: Julius C. Amabo)

Physical Characteristics: The breed is large and long-lopped with average measurements of 85 cm at the withers, with males measuring 75–85 cm, while females are 65–75 cm. The face profile is convex, the tail is long and thin. The body is covered with a coat of short coarse hair that is coloured entirely black or brown, beginning from the anterior forehead to the limb-abdominal girth line and the white posterior (Fig. 6.5). Ears are long, large and pendulous. Rams have large spiral horns while ewes are polled (Wilson 1991; Njuki and Mburu 2013).

Adaptive Characteristics: The breed is long-legged and adapted to semi-arid monomodal rainfall lowlands to arid zones. It thrives in hot and dry environments, with a poor survival rate beyond this ecological zone. The Uda is well adapted to extensive grazing and well-known for its trekking abilities (Adu and Ngere 1979).

Typical Production Systems and Production Characteristics: The breed is mostly raised for meat under the agropastoral and pastoral transhumant management systems. Mature live weights range from 45 to 65 kg for rams and 35 to 45 kg for ewes (Wilson 1991; Adu and Ngere 1979). Other production characteristics reviewed by the latter authors include *first oestrus:* 351 days in Niger; *Oestrus cycle:* 16.8 ± 0.06 days (heat lasts 33.2 ± 3.1 h); *Ovulation rate:* 1.3; *gestation period:* 154.8 days; *age at first lambing:* 15–17 months on station (Niger), 448 days (314–662) in Cameroon; *lambing interval: 270* days (Shika, Nigeria); average litter size: 1.1; *birth weight:* 3.5 kg on station (Niger); males 3.9 kg, females 3.5 kg (Shika, Nigeria); *weight*

for age: on station in Niger, weights at 30, 90 and 180 days increased from 7.3, 13.6 and 20.4 kg in 1981 to 11.0, 18.9 and 27.0 kg in 1987, probably due to better management; *average daily gain from birth to 18 kg*: single males 150 g (114–192), twin males 110 g (75–174 g), single females 140 g (79–170 g), twin females 113 g (101–142 g) in Katsina (Nigeria); *Milk yield* on station in Niger was estimated at 60 litres in 150 days. *The dressing percentage for meat was* 48–50% on station in Niger and 38–41% at 13–14 months with a carcass weight of 11.5 kg at Shika (Nigeria).

Yankasa

Distribution and Classification: Yankasa sheep (Fig. 6.6) is part of the West African Sahel (long-legged group), distributed from Senegal to Cameroon, with the possibility of some admixture among sheep from farther south (Wilson 1991). Yankasa is widely distributed, making up approximately 60% of the Nigerian flock in Northern Guinea and Sudan Savanna, where it is locally called white Fulani or 'Hausa'.

Physical Characteristics: Yankasa is intermediate in size between Uda and West African Dwarf sheep (Adu and Ngere 1979), 68 cm at withers, coat is white with black patches around the muzzle, ear, eyes and occasionally the feet, ears are relatively short and semi-pendent, rams have curved horns and heavy hairy white mane while ewes are polled and some may have tassels on the neck (Fig. 6.6).

Adaptive Characteristics: They are adapted to sub-humid and semi-arid regions, extending to the Northern Guinea savanna in the south.

Typical Production Systems, Husbandry Practices and Production Characteristics: The Yankasa is maintained mainly in agropastoral and pastoral management systems. In the Fulani agropastoral system near Zaria (northern Nigeria), 70% of families keep an average of 12.5 sheep with a flock structure of 76% females, which are allowed to graze with cattle. Reproductive characteristics reviewed by Wilson (1991) include: *Age at first oestrus*: 238 days, *weight at first oestrus*: 18.4 ± 0.4 kg, *oestrus cycle*: 18.1 ± 1.7 days; *heat:* 25 ± 2.2 h and *ovulation rate* of 1.36 ± 0.34. Other estimates include 575 ± 9.6 days for *age at first lambing*, 249.8 ± 2.7 days for *lambing interval* (Bemji et al. 2001a), 1.22 for litter size (Bemji et al. 2001b), 2.48–2.91 kg *birth weight* (Bemji et al. 1996; Afolayan et al. 2006), 31 kg at maturity (25–40 kg for ewes and 35–50 kg for rams), and 42% (*dressing percentage*) at 30 kg live weight (Review by Wilson; 99 (Wilson 1991)). *Heritability* estimates of 0.07 (*litter size*), 0.41 ± 0.08 (*birth weight*), 0.12 ± 0.07 (*litter birth weight*), 0.99 ± 0.38 (*age at first lambing*) and 0.73 ± 0.26 (*lambing interval*) (Bemji et al. 1996, 2001a, c).

D'man

Origin, Distribution, Classification and Population Statistics: The D'man (Fig. 6.7) is also known as the D'men, Damana, Demnan, Demmane, Demane and Tafilalet (DAGRIS 2007). As reviewed by Boubekeur in 2015 (Boubekeur et al. 2015), D'man is distributed within the pre-Saharan regions of Southern Maghreb, around the oases of Errachidia, Ouarzazate, Dades and Draa (South-eastern Morocco), oases of Saoura, Touat and Gourara (Southwestern Algeria) and Tozeur and Kebili in Southern Tunisia. Over 617,000 D'man sheep are raised in the oases of South Morocco (Boujenane et al. 2013). The breed is classified among the endangered breeds.

The origin of this breed has always been disputed, and a study using 30 microsatellites (Gaouar et al. 2015) concluded that this breed may be the result of a cross between the Sid Aoun race and a white race from the North of Algeria. In addition, there is a homonymy of two populations evolving in the Algerian southwest, one at the level of the Saoura and the other in the region of Adrar, both bearing the same name 'D'men'. However, they may constitute different breeds that may need further studies.

Physical Characteristics: D'man is a large goat breed with 63.9 cm (females) and 72.3 cm (males) height at wither, coat colour varies (white, black and brown with their combinations), black or black in combination with other colours are predominant (Boubekeur et al. 2015). Most animals have a white spot on the head, both sexes are polled, the tail is thin, long (42.9 cm) with a white tip, and the ear length is 13.6 cm (Fig. 6.7).

Adaptive Characteristics: D'man is mainly a sheep breed of the Oasis in Morocco, Algeria and Tunisia but tolerates Saharan conditions.

Typical Production Systems and Production Characteristics: The breed is mainly raised for meat and milk under pastoral and family farming systems and in a few breeding farms. It has high reproductive performance, including high prolificacy of 200%, early puberty (6 months) and a long breeding season (from May to February), although the growth rate is low (140 g/day) (Boujenane et al. 2013). Conception rate, litter size at birth, litter size at weaning, litter weight at birth, litter weight at weaning, gestation length and ewe's body weight averaged 94.4%, 2.38 lambs, 2.03 lambs, 6.23 kg, 39.6 kg, 149.9 days and 44.8 kg, respectively.

Fig. 6.7 D'man. (From Djaout et al 2017, licensed under CC-BY 4.0)

Ouled Djellal

Distribution: Ouled Djellal, also known as the Arab white sheep (Fig. 6.8), is a dominant sheep breed in Algeria, accounting for more than 63% of the Algerian sheep populations (Gaouar et al. 2017). Due to high productivity, the breed is frequently used for cross-breeding with other local Algerian sheep breeds. This has resulted in genetic admixture with Rembi and Taâdmit breeds (Gaouar et al. 2015).

Physical Characteristics: Ouled Djellal is a large, long-legged sheep, with a withers height of 80.13 cm and 91.40 cm for females and males, respectively. The coat colour is predominantly off-white or pale-yellow, while the head and limbs are either white or white speckled with fawn (Harkat et al. 2015). The males are horned, with the horns being small (budded) or spiral with a lateral orientation. The majority of females (92.21%) are polled. Where horns are present in females, they are either small or curved. The ear length varies and can be either short, medium or long. The ear shape can either be semi-horizontal or drooping, the latter being the characteristic in the majority. The forehead profile is slightly hooked in the majority of sheep. The tail length varies between short, medium and long (Fig. 6.8).

Adaptive Characteristic: The breed is adapted to arid climates.

Typical Production Systems and Production Characteristics: Ouled Djellal is managed under sedentary or semi-sedentary systems with the use of one or two seasonal pastures and a transhumant farming system. The breed is mainly raised for meat and wool. Mature body weight is 61.27 kg for females and 95.87 kg for males (Harkat et al. 2015).

Ara Ara

Distribution and Classification: The Ara Ara belong to the West African Sahel or long-legged breeds of sheep distributed in central and south-central Niger.

Physical Characteristics: The breed is similar to the Uda sheep in physical characteristics.

Adaptive Characteristics: The Ara Ara is adapted to semi-arid conditions.

Typical Production Systems and Production Characteristics: The breed is managed under agropastoral and pastoral systems for meat. Litter size is 1.18 (84.6% single, 13.0%, 2.4% triplet). Multiple births are common for arid zone sheep. Birth weight is 2.7 kg with single males, twin males, single females and twin females weighing 3.0 kg, 2.4 kg, 2.7 kg and 2.3 kg, respectively, on the Maradi station (Wilson 1991).

Peul-Peul

Distribution and Classification: Fulani (English) and Foulbé are synonyms for the breed, which constitutes part of the West African Sahel or long-legged sheep found in central Senegal (Wilson 1991).

Physical Characteristics: Peul-Peul (Fig. 6.9) is a medium-sized sheep breed of about 65–75 cm at the wither and a live weight of 30–50 kg at maturity. The coat colour varies; however, most animals are white with black or red spots or entirely red. The coat is stiff and short. Loosely spiralled horns are present in males, while females are polled.

Adaptive Characteristics: The sheep are adapted to semi-arid to sub-humid zones within the Sahel and Sudano-Sahel regions.

Typical Production Systems and Production Characteristics: Peul-Peul is managed under pastoral and agropastoral systems for meat. Reproductive includes *Age at first lambing*: >24 months; *Lambing interval*: 12 months in Senegal's traditional system and 7.3 months for sheep raised on station; *Birth weight*: male 3.1 kg and female 2.9 kg (for dams provided supplementary feeding). *Average daily gains*: 0–40 days: 124.4 g, 40–180 days: 110.6 g and the *dressing percentage* was estimated at 50%.

Sudan Desert Sheep

Origin, Distribution and Classification: Sudan Desert sheep (Fig. 6.10) are the most common sheep in Sudan and are found in all parts of the country except the southern regions. They are alternatively called Arab, Northern Sudanese, Desert Sudanese, Sudanese Desert (Wilson 1991; Gatenby 2006). Numerous tribal types are recognised in Sudan, which include Dubasi, Watish, Kababish, Baqqara, Shugor, Ashgur, Butana, Beja, Drashiani, Gash, Barka (Shukria) and Hamale (Wilson 1991; DAGRIS 2007). They are found at 10 °N of Sudan, extending eastwards into Eritrea and westwards into Chad (Wilson 1991; Gatenby 2006). Other populations include Gezira and perhaps Barka and Wollega, found in Ethiopia. A crossbred ecotype (Sudan Desert x Southern Sudan) was recognised in the central belt of Sudan, extending eastwards into Eritrea and westwards into Chad within different ecological regions (arid, semi-arid and riverine).

Physical Characteristics: Sudan Desert sheep is a large breed (Fig. 6.10) of up to 80 cm or more at the withers, depending on the tribal type, with adults weighing 60 kg (male) and 50 kg (female). As reviewed by (Wilson 1991), the head is strong, the forehead broad and flat with a convex profile (the Dubasi have a markedly convex profile) with eyes set high. Sheep from eastern Sudan are polled, but 5% of males and females from the west are horned (spiral type), with lengths of up to 60 cm. Ears are medium to long (12–18 cm) and drooping. Toggles are present in both sexes in about 10% of sheep. The chest is well developed with a fairly heavy and long neck. The withers are prominent and broad in most types, with legs long, sometimes very long, and lightly fleshed. The sacrum is usually higher than the withers. The group is fairly well developed. The tail is thin and long, with variable amounts of fat at the base or extending down depending on the tribal type. The tail length can be 60% of the withers height to greater than the withers height trailing the ground.

The coat is fine to coarse and short to long with variable coat colours depending on the tribal type (Fig. 6.10). The Shugor are moderately large, with coat colour ranging from light to dark

brown and sometimes patches of wool beneath the hair. They are found along the White Nile and areas to the west. Herds of Shugor sheep are predominant in the western part of Gezira. They travel more than the Dubasi sheep, which are the prototype sheep of the northern part of the Gezira area and are found in greater numbers in the villages of Dubaseen tribes (hence Dubasi) in El-Fawar, Umbusha, Selaim, Kab El-Gidad and north of Khartoum, where they are called Butana. Watish sheep are smaller than Shugor and Dubasi.

Adaptive Characteristics: Sudan Desert sheep are hardy and adapted to arid, semi-arid and rive rain areas.

Typical Production Systems and Production Characteristics: Sudan Desert sheep are mainly raised in large flock sizes for meat, milk and skins under pastoral, agropastoral and urban systems. Flock structure favours meat or milk production, constituting 77.8% females (55.8% breeding females), males 22.2% (4.2% >15 months). Reproductive parameters as reviewed by Wilson (1991) include *Age at first lambing*: 13–15 months in the Southern Darfur traditional system; *Lambing interval*: 275–426 days; *Litter size*: 1.14–1.22 depending on the type, *Annual reproductive rate*: 1.11 lambs per ewe on station; 1.50; *Oestrus cycle*: 17–21 days; *Duration of heat*: 25 h; *Gestation period*: 147–166 days; *Birth weight*: males 4.1 ± 0.63 kg, females 3.9 ± 0.66 kg (Shugor and Dubasi heavier than Watish); *Weight for age*: 30 days—7.4 kg, 90 days—14 kg; *Average daily gain*: 0–30 days: 136 g, 30–120 days: 110 g; *Lactation length*: 188 days on station; *lactation yield*: 137 kg; *Milk composition*: estimates were reported for total solids (12.4%) and fat (4.28%); *Dressing percentage*: 49.1% and 46.0%, respectively, at 32.3 kg and 34.9 kg live weights on low and high fibre diets, while 52.7% was recorded for an empty body weight of 30 kg.

Black Maure

Origin, Distribution and Classification: Synonyms include Moor, Mauritania and Arab (DAGRIS 2007). The breed has been reported to have originated as part of the West African Sahel (long-legged group), with the likelihood that it descended from Rio de Oro sheep of northern Mauritania, which in turn descended from the Maghreb type in Morocco (Wilson 1991). Subtype includes the Zaghawa (Arid Upland) of northwestern Darfur and eastern Chad. Black Maure is owned by Moor tribes in southern Mauritania (Hodh region), northern Mali in Nara, Nioro and Niono areas and eastwards to the western border of the Niger flood zone, and northern Senegal.

Physical Characteristics: The Black Maure is a large sheep breed of 75–90 cm at the withers (male 80 cm, female 74 cm) with a mature weight of 45 kg (male) and 32 kg (female) (Wilson 1991). The coat colour is black with a white tip to the tail. The breed has a strong head (forehead flat), a convex profile in males but less in females and well-developed tear glands. Females are polled, while horns are well developed in males, triangular in shape, spiral outwards from the head and up to 30 cm long. Horns have less pronounced ribs in Zhagawa. Ears are long (20 cm in Maure), medium (12 cm in Zhagawa), broad and pendulous. Toggles are long and present in a few of both sexes. They have a long and thin neck, a narrow and shallow chest and a long and dipped back. The tail is long (36 cm), thin and falls below the hocks. The coat is long with coarse, stiff black hair in loose ripples on a softer undercoat.

Adaptive Characteristics: The Black Maure is adapted to arid areas with low or high seasonal rainfall. The areas include Northern Sahel and Saharo-Sahelian zones with annual grasses (Aristida, Cenchrus), some perennials and scattered acacia scrub.

Typical Production Systems and Production Characteristics: The main husbandry system for Black Maure is pastoral. The breed is mainly raised for hair, meat, milk, skins and pelts. Reproductive and production characteristics as reviewed by Wilson (1991) include *Age at first lambing*: 12–18 months; *Lambing interval*: 8–10 months; *Litter size*: 1.03 (multiple births of 2–4%); *Annual reproductive rate*: 1.4; *Gestation length*: 153 days (Sudanese Zaghawa); *Birth weight*: 3 kg; *Weight for age*: 5 months (16.0 kg), 12 months (24.0 kg) and 36 months (32.4 kg);

Hair yield: multiple clips yield (200 g per year); *Fibre length* (3.3–10 cm) and *Fibre diameter* (26.6 um); *Dressing %*: 35–40 in West Africa and 39–42 in Chad.

Touareg

Origin, Distribution and Classification: Synonyms for Touareg sheep include Grand Targui (Ara-Ara, Argooradji), Petit Targui and Tuareg (DAGRIS 2007). The breed originated as part of the West African Sahel (long-legged group). A smaller 'Touareg' sheep (sub-type) is sometimes distinguished in Gourma (Mali). The breed is distributed North-east of Mali from the top of the Niger bend and Timbuctoo, north to the Adrar n'Iforas at about 19°N and eastwards to Niger, from Niamey and Dosso to the Aïr region in the north (Wilson 1991). This breed is also very popular in the great south of Algeria, where it is very appreciated (Djaout et al. 2017).

Physical Characteristics: The Touareg sheep is a large animal measuring 75–80 cm at the withers and weighing 40–60 kg. The coat colour could be white and spotted or red. The coat is of short, stiff hair. A review by Wilson (1991) shows that the head is strong with a prominent forehead and convex profile. The muzzle is narrow and the eyes are less prominent. Females are polled, while horns in males are strongly ribbed and spiralling backwards. Ears are 15 cm in length, and toggles are present in both sexes. They have a long neck with fat folds at the nape in males. Withers is prominent, and the chest is narrow and shallow, with a girth circumference hardly exceeding withers height. The back is straight and long. Rump is less sloping compared to neighbouring Maure and Toronké types. Legs are long with flat thighs. The tail is of medium length, reaching the hocks. The udder is well-shaped with long, well-spaced teats (Wilson 1991).

Adaptive Characteristics: The Touareg sheep is adapted to semi-arid and arid to extremely arid conditions.

Typical Production Systems and Production Characteristics: The Touareg sheep is raised for meat and milk and is managed under pastoral, transhumant, nomadic and agropastoral systems to a lesser extent. Flock size is fairly large, at about 50–100 and mostly raised for meat production in Mali and for milk production in Niger. Reproductive and production traits, as reviewed by Wilson (1991), include *Age at first lambing*: 2 years; *Lambing interval*: ≥365 days; *Litter size*: 1.03, *Annual reproductive rate*: 0.59; *Lifetime production*: 4% of ewes produce more than 4 lambs; *Milk yield*: 200–400 g/d (dry season); 400–600 g/d (wet season); *Dressing percentage*: 46%.

6.5.2 Thin-Tailed Coarse Wool Sheep of Africa

Thin-tailed coarse wool sheep have been given the collective name Maghreb by Epstein in 1971 (Epstein 1971) and are distributed in the northern African mountainous regions of Algeria, Morocco and Tunisia, along the central Niger River delta and in east African countries of Eritrea and South Sudan. They probably evolved from the original thin-tailed hair sheep populations (Devendra and McLeroy 1982). Examples of these breeds are the Macina, Barbarin, Toubour and Dané Zaïla. Their bodies are covered with a coarse carpet-type wool, which is often white or coloured, from which the pastoralists use to make blankets and coarse cloth. They range in size from small to medium, with an average withers height of 60–80 cm, and have a heavy head, convex face profile and pendulous ears. Rams have large spiral horns that either curve backwards or slightly upwards. Ewes can be polled or have small horns (Rege et al. 1996; Epstein 1971).

6.5.2.1 Macina

Origin, Distribution and Classification: Synonyms or subtypes of Macina include Koundoum, Goundou (in Niger) and Tillabery Sheep (in Niger) (Wilson 1991; DAGRIS 2007). The breed is mainly found in the central Delta of Niger and Mali, with Macina being the Fulani name for the Niger River flood zone. According to Wilson (1991), they possibly descended from the wooled thin-tailed sheep from North Africa and migrated to the present area with the Moors and Moroccans during the conquest of Timbuctoo

in the fifteenth and sixteenth centuries. It was previously mistakenly believed to have descended from the Karakul breed or from various crosses of Merion with Syrian or Barbary sheep. Three other types of 'wool' sheep in West Africa include Hadina (large black sheep kept by the Toubou in the extreme east of Niger); Dané Zaïla (very small white sheep from the same area kept by Arabs) and wool sheep of West Kanem found in the north and west of Mao in Chad. The Macina breed is confined to the floodplain of River Niger in central Mali (± 50,000 km^2) along a narrow band on both sides of the river to Niamey (Wilson 1991; Gatenby 2006).

Physical Characteristics: The Macina sheep is a medium-sized breed averaging 60–80 cm at the withers. The adult average weight is 40 kg in males and 30 kg in females. The forehead is broad and straight with a straight profile or slightly convex in males. There is no interorbital depression, and supraorbital processes are pronounced. The nose is narrow with a longer upper jaw compared to the lower one. Horns are well developed with deep grooves in males (65%) and a classic spiral 'ram's horn' shape. A small percentage (0.5%) have multiple horns, although in the early twentieth century, and 4.0% had multiple horns. In the present-day population, 8% of females have weak horns or scurs. The ears are medium (12 cm long), wide and pendulous. Toggles, which were initially absent in the original stock, are found in 15% of animals. The neck is short, and the chest is shallow and narrow. The withers are prominent, while the back is straight. The croup is tucked and thinly fleshed. Legs are long with light flesh. The tail is thin and descends below the hocks. The coat colour is commonly white, diversely spotted with black or red colours, especially around the eyes and ears. The body, forehead, knees and hocks are covered with a coarse wool coat that is mixed with hair, but the underside is bare. Goundoun is similar in most of these features.

Adaptive Characteristics: The Macina sheep thrives within humid areas associated with the seasonal flooding cycle of the Niger River ecological zone, which forms its main distribution area.

Typical Production Systems and Production Characteristics: The Macina sheep is kept by Fulani, who are the main inhabitants of the Niger River floodplain area. They keep the Macina mainly for wool, milk and meat production under pastoral and agropastoral systems. Transhumant management involves short treks outside the flood zone when flooding is at its peak between July and October. Flock sizes are generally large. Reproductive and production parameters as reviewed by Wilson (1991) include *Age at first lambing*: 371–766 days; *Lambing interval*: 170–485 days; *Multiple births*: twins: 3.1%, triplets: very rare; *Litter size*: 1.03; *Birth weight*: 2.7 ± 0.62 kg; *Weight for age*: 90 days—10.3 kg, 365 days—24.4 kg; *Mature weight*: males—60 kg; *Lactation length*: 135 days (range 85–165); *Lactation yield*: 50 kg; *Wool yield*: 2 clips per year with total of 685 ± 42.8 g (males 836 ± 52.5 g, females 534 ± 65.0 g); *Fibre length*: 4.6 cm; Fibre diameter: 39 um; about 10 crimps per 100 mm; resistance is 14 g with very little grease. The fibre is used for blankets and coarse cloaks. *Dressing %* is 40 with low-fat meat.

6.5.2.2 Berbere

Origin and Distribution: Azoulai Berber wool and A'arbia, Zoulay are synonyms of the Berbere sheep (Fig. 6.11). The Berbere breed is the oldest Algerian sheep breed. It is distributed across the mountainous chain of northern Algeria in Bouhadjar, Souk Ahras, El-Tarf, Annaba, along

Fig. 6.8 Bélier Ouled Djellal ram at Biskra. (From Djaout et al. 2017; licensed under CC-BY 4.0)

the Algerian-Tunisian borders, Tlemcen, Souk Ahras, Maghnia, Jijel (Collo), Edough, Ouarsenis and the mountains of Tiaret. In Algeria, it is known as A'arbia (Djaout et al. 2017). It is also found in the upper Moulouya Valley of Morocco. In Morocco, the Berbere breed origins are believed to be from the Tousint and Berber breeds (Mason 1996). It is called '*A'arbia*' by the breeders because it was believed to have originated from the Arabian Peninsula.

The Berbere sheep are reared in small flocks that do not usually exceed 20 heads per breeder. The current distribution area of Berbere sheep is much smaller than what was reported by Chellig (1992). Recent studies have shown that in the mountainous region of Jijel, the Berbere sheep was replaced by the Ouled Djellal and Hamra breeds as a result of a great reduction in the artisanal activity, which uses Berbere's wool for the manufacture of burnous, other traditional clothing and leather goods. The reduction in this traditional activity has led breeders to replace this breed with the Hamra breed and, to a greater extent, with the Ouled Djellel breed (Gaouar and de La Biodiversité 2009). Berbere sheep have been classified as an endangered breed.

Physical Characteristics: The Berbere sheep is a small animal with bright, shiny white wool (Azoulai). The Berbere sheep is described as a robust animal. The coat colour could be white (Fig. 6.11), brown and sometimes black or a mixture of brown, white or black and white. The head is short and concave. Ears are medium, thin and horizontal. The wool is white and long, sometimes mixed with brown or black, not crimped, with an open, drooping fleece.

Adaptive and Special Genetic Characteristics: Berbere ewes are good mothers. The sheep are milked and mainly used for consumption at the household level. Breeders prefer this breed for its hardiness and due to the fact that it is resistant to parasites and adapted to the extreme cold. Meat quality is poor (Djaout et al. 2017).

6.5.2.3 Hamra

Distribution, Classification and Population Statistics: The Hamra (Fig. 6.12) is an indigenous Algerian breed, known locally as '*Beni-Ighil*' in the Moroccan High Atlas (Morocco), where it is reared by the *Beni-Ighil* tribe, by which it is named (Gaouar et al. 2015). In Algeria, however, it is known as '*Deghma*' because of its dark red colour. The Hamra's natural habitat is from Chott Chergui to the Moroccan border (Chellig 1992).

The population was 3.2 million head at the beginning of the 1990s (Chellig 1992), with the number increasing to 500 million head in 2003 (Feliachi 2003). However, the population has decreased to under 100 million in recent years (Ayachi et al. 2017). This decrease has been mainly attributed to the massive introduction of the Ouled Djellal breed by breeders, resulting in the replacement of the Hamra breed in the main distribution areas (Gaouar et al. 2015). Hamra sheep is currently located in the western steppe, up to the Moroccan border, at the level of the Wilayas of Saïda, El Bayed and Tlemcen (Djaout et al. 2017).

Fig. 6.9 Peul-Peul sheep in the sylvo-pastoral zone of Senegal. (From Ndiaye et al. 2018, licensed under CC-BY 4.0)

Fig. 6.10 Sudan Desert sheep reared in the semi-desert belt of Sudan. (From Ali et al. 2016, licensed under CC-BY 4.0)

Physical Characteristics: Hamra sheep is medium-sized and has a very close phenotype to the Moroccan *Beni-Iguil* breed (Benoudifa 1990), with which it shares the same origin (Gaouar et al. 2015; Chellig 1992). The body is covered with white coarse wool, with a fineness of 74.17 ± 49.44 µm (Belharfi et al. 2017a). The rams have medium-sized horns with black streaks (Djaout et al. 2017). The head is dark coloured, with three main colours being reported, namely, dark mahogany to an almost black, dark mahogany and light mahogany (Fig. 6.12) (Djaout et al. 2017).

Adaptive Characteristics: It is very popular for its hardiness, but above all, for the flavour and finesse of its meat.

Production Characteristics: The Hamra breed (also referred to as *Oranie* in the French market) has the ideal conformation of a meat-producing sheep and bears a remarkably fine frame. The medium size is the main reason why this breed is being replaced by the Ouled Djellal breed. The Hamra ewe is characterised by good milking ability, with milk production under the medium category and with a maximum production of between 50 and 60 kg during 4–5 months of lactation (Chellig 1992).

6.5.2.4 Darâa

Distribution: The Darâa is an indigenous Algerian breed distributed throughout Algerian territory. Although currently experiencing low numbers, it is found in flocks of mixed breeds and races. It closely resembles the French breed *Noire Velay (*Daniel 2000*)*, the Tunisian breed (Noire de Thibar) and a variety of the D'man breed described by Boukhliq (2002).

Physical Characteristics: The Darâa breed has a completely black head and legs. The body is covered with wool, characterised as closed or semi-closed, brown in colour and measuring 45.00 ± 19.115 µm (Belharfi et al. 2017a). The head is short and thin, the muzzle is straight, the limbs are thin, and the tail is medium or long; horns are absent in females, but males can be horned (Djaout et al. 2017).

6.5.2.5 Beni-Ahsen

Distribution: The Beni Ahsen is a Moroccan sheep breed cherished for its wool traits. It has the weightiest fleece and finest wool compared to other local breeds. Studies have indicated that the Beni Ahsen may be an ancestor of the Merino and specifically the Iberian Merino (Kandoussi et al. 2022).

Physical Characteristics: The Beni Ahsen is a thin-tailed breed of 80–100 cm and 70 cm height at the withers for males and females, respectively. The face is brown with strong head conformation. Males are horned while females are polled. The fleece is white, neck long with a pronounced fold and dewlap. Shoulders are high with an appearance of a hanging rump. Studies from the late 1970s through mid-1980s recorded 3.54 kg and 3.43 kg as average birth weights for males and females, respectively, and 18.6 kg and 17.0 kg at 90 days for males and females, respectively (Boujenane 2002). A review by the author showed that the weighted average for adult ewes (≥2 years) was 44.8 kg, with adult rams averaging 60–80 kg.

Breeding Practices and Production Characteristics: Beni-Ahsen ewes are seasonally bred between May and August to lamb between

January and February (Boujenane 2002). As reviewed by the authors, ewes lamb for the first time at 24.9 months with a gestation length of 149.9 days. Studies from the mid-1970s to the mid-1980s reviewed by the authors recorded average fertility (85.6%), prolificacy (104%) and lamb survival rate from birth to 90 days (93%), with 81% of lambings concentrated between November and February.

Lactation performance as reviewed by Boujenane (2002) showed that average milk yields of 70.9 kg and 64.4 kg were reported for two different 10-week lactation studies, while 57.4 kg was obtained using weight differences (WD) of lambs before and after suckling during a 12-week lactation. A higher average yield of 113.7 kg was obtained using oxytocin. A 14-week lactation study realised 81 kg under the WD method, while 132 kg was obtained using the oxytocin method. Dry matter, fat and protein contents ranged from 22.1 to 22.3%, 9.9 to 10.6% and 5.0 to 5.5%. Beni Ahsen sheep are treasured for their wool quality and quantity. Average fleece weight and fibre fineness score were, respectively, 2.7 kg and 52.9 kg.

6.5.2.6 Timahdite

Location: The Timahdite is one of the main indigenous Moroccan sheep breeds. It is the country's best meat breed and is valued for its good conformation, ease of fattening, carcass yield and high milk production (Boujenane 2002). The breed is very hardy with excellent adaptation.

Physical Characteristics: The Timahdite has a brown face, white coarse fleece and white legs. Height at withers is estimated at 50–55 cm for females and 60–70 cm for males (Boujenane 2002). The tail is thin, and horns are present in rams, but ewes are polled.

Breeding Practices and Production Characteristics: Timadite ewes are seasonally bred between May and September to lamb between January and February (Boujenane 2002). Review of reproductive traits by the author revealed that litter size at birth ranged from one to three lambs. Lambings of single litters represented 93.3%, twin litters 6.5% and triplets 0.1%; age at first lambing: 48 months; average gestation length: 148 days; fertility: 82.4%; prolificacy: 104%; lamb survival from birth to 90 days: 84.5%; body weights: 3.31 kg vs 3.25 kg for males and females at birth, 17.6 kg vs 16.4 kg at 90 days, 37.7 kg vs 36.8 kg at 1 year and 57.2 kg vs 40.6 kg for adult rams and ewes (≥2 years); average daily gain: 171 g; feed conversion: 6.2 kg feed/kg weight gain; average slaughter weight: 29.8 kg at 221 days of age; average carcass weight: 14.4 kg and dressing %: 48.1.

Lactation yield estimated by the weight difference of lambs before and after suckling was 84.3 kg. Dry matter, fat and protein contents of milk from oxytocin-treated ewes averaged 24%, 11.7% and 5.1%, respectively, with a higher average milk yield of 123.4 kg for a 12-week lactation period. Fleece weight averaged 2 kg, fibre diameter was 31.6 mm and staple length was 8.75 cm.

6.5.2.7 Sardi

Location: The Sardi sheep is a prominent breed reared in Morocco. It is highly regarded nationally, and the male is highly sought after for the Sheep Sacrifice Festival (Aid Adha). In Morocco, the main local breeds, Timahdite, Sardi, Boujaad and Beni Guil, show similar performances, particularly concerning characters of economic interest.

Physical Characteristics: The Sardi sheep is characterised by a white head that is devoid of wool. Black spots are present around the eyes, muzzle and the tips of the ears and legs. The belly and the limbs are devoid of wool. The muzzle is straight in the ewe, broad and slightly arched in the ram. The horns (absent in females) are well developed and open in males. The fleece is closed without spots or jars with short and tired wicks. The adult weight in males varies from 70 to 100 kg and in females from 45 to 60 kg. Adult height at withers varies from 80 to 90 cm in males and 55–65 cm in females.

Adaptive Characteristics: The Sardi breed is rustic and well adapted to poor pastures, especially those of the Central West plateaus.

Breeding Practices and Production Characteristics: The breed has low prolificacy (estimated at <120%). To increase its productiv-

ity, the breed is often crossed with other breeds. Development of efficient cross-breeding schemes, such as industrial or double-decker cross-breeding involving the Sardi breed, particularly outside its cradle area, would help to cope with growing demand from more Moroccan consumers, especially in large urban centres where consumers demand quality meat with less fat (Boujenane 2002).

A 12-week lactation yield of Sardi ewes obtained by weighing lambs before and after suckling averaged 59.3 kg, while two 8-week lactation studies had a weighted average of 55.4 kg (Boujenane 2002). The average milk yield at 10 weeks of lactation by the oxytocin method was 68.5 kg. Suckling in combination with hand milking prolonged the lactation period to 20 weeks with an average milk yield, dry matter content, fat content and protein content of 112.7 kg, 16.9%, 4.6% and 5.8%, respectively. Average fleece weight was estimated at 2 kg from four studies, while one of the studies recorded 6.43 cm for staple length (Boujenane 2002).

6.5.2.8 Beni Guil

Distribution, Classification and Population: The Beni Guil (Fig. 6.13) is one of the main Moroccan local breeds included in the National Programme for Genetic Improvement since 1980. The Beni Guil breed is found located around the Oriental plateaus, namely, Tendrara, Bouarfa and Figuig. Its name comes from the Beni Guil tribes who own this breed. Its population was estimated at 1.2 million in Morocco in 2018.

Physical Characteristics: The Beni Guil (Fig. 6.13) is a medium-sized sheep of 60–65 and 40–50 cm height at the withers for males and females, respectively (Boujenane 2002). Phenotypically, it has white fleece, brown limbs, a brown large face and belly (Belhaj et al. 2021), resembling Beni-Ahsen. It has a rectangular shape, a short neck and a fleece of medium fineness. The breed is thin-tailed, and rams have fairly well-developed spiral horns (Boujenane 2002).

Adaptive Characteristics: The Beni Guil breed adapts well to the poor vegetation of the Oriental plateaus (Tendrara, Bouarfa and Figuig) and can acclimatise in other regions of Morocco.

Breeding Practices and Production Characteristics: Beni guil ewes are seasonally bred between May and September to lamb between January and February (Boujenane 2002). Review of reproductive traits reported by the author includes age at first lambing: 25.3 months; gestation length: 149.3 days; mean fertility: 85.9%; prolificacy: 109%; 90-day litter weight: 16.5 kg; single litter: 94.1%; twin litter: 5.9%; lamb survival from birth to 90 days: 94.3%; average birth weights: 3.32 kg for males and 3.14 kg for females; 90-day weight: 16.1 kg and 14.8 kg, for males and females, respectively; adult body weights: 70–90 kg and 45–50 kg, respectively, for males and females; average daily gain and feed conversion for lambs: 215 g and 5.5 kg feed/kg weight-gain, respectively; average slaughter weight at 160 days: 29.1 kg; carcass weight: 13.6 kg and dressing percentage: 47.7%.

Beni Guil ewe milk yields at 8, 12 and 20 weeks of lactation were estimated at 40.3 kg, 52.3 kg and 97.9 kg, respectively, while mean dry matter, fat and protein contents at 12 and 20 weeks were 19.5 g, 16.4 g and 5.4 g, and 8.4 g, 4.3 g and 5.6 g, respectively (Sefiani 1980; Battar 1983; Boujenane et al. 1996). These studies used the method of weighing lambs before and after suckling to estimate yield. Various studies have shown an average fleece weight of 1.70 kg. An average staple length of 7.12 cm has been reported (Abdelali 1988).

6.5.2.9 Tadla

Distribution and Classification: The Tadla is a Moroccan sheep breed that is maintained in its pure state on the plateaus of Kasba-Tadla, Oued-Zem and El Borouj. The breed is part of the concave, arched, sublongilinear, eumetric type, with white fleece and pigmented ends.

Physical Characteristics: It is a fairly large sheep, ranging between 85 and 90 cm in height at the withers. The breed has a strong frame (9.5 cm around the barrel) and a heavy head bearing large and powerful horns that sometimes weigh up to 500 g each. The neckline is long, thick and has a slight dewlap, and the top is quite wide. The thigh

is muscular and slightly flat. The adult average weight for rams ranges between 75 kg and 85 kg. Lambs at 18–20 months old weigh between 50 kg and 55 kg. Birth weights as high as 6 kg have been reported. The cream-white fleece is closed, and the locks are square and tight. The sheep produces a pale yellowish-white coloured wool that is long, fine and wavy strands with an average staple length of between 7 cm and 9.5 cm and an average shearing weight of 1.5–1.6 kg and sometimes reaches 3.8 kg (Ben Lakhal 1995).

The Béni-Meskine sheep, a variety of the Tadla breed, is distinguished from the Tadla breed by having a less fine fleece and a better conformation. This breed is distinguished from the Sardi (previously described) by its white pigmented head with black around the nose and around the eyes.

6.5.2.10 Arrit

Origin and Distribution: The Arrit breed, an indigenous breed from Eritrea, is thought to be an intermediate between the Sudan Desert and Ethiopian Highland sheep reared by the Arab tribes located in the Keren region in Northern Eritrea (Mason and Maule 1960). It phenotypically resembles the Dongola sheep of Sudan. It is partially hairy with some coarse wool and has a seasonal accumulation of fat at the base of its tail, suggesting its origin may be related to the woolled thin-tailed sheep breeds of North Africa and the Sahara, as well as the fat-tailed sheep of the East African highlands.

Physical Characteristics: The breed is typically polled; however, some rams have open spiral horns. The breed is medium-sized with semi-pendulous ears. The coat is white. The facial profile is nearly straight, and the tail is thin, long and straight, extending to below the hocks.

6.5.2.11 Saidi

Location: The Saidi sheep is found in Upper Egypt, especially in the Assiut governorate.

Physical Characteristics: The body is black (Fig. 6.14) or dark brown (Fig. 6.15), but sometimes creamy white and black and white individuals are found. The head is large with a curved nose. The ears are medium-sized. The head is covered with wool. The neck is long, and both sexes are polled. Saidi has a long, cylindrical, fat tail.

Fig. 6.11 Berbere sheep of the Bouhadjar mountains (El-Tarf), Algeria. (From Djaout et al. 2017, licensed under CC-BY 4.0)

Production Characteristics: Mature body weights for rams and ewes average 50 kg and 35–45 kg, respectively. Birth weights range from 2.5 to 3.1 kg, while weaning weights average 13 kg. The mean average daily weight gain from birth to weaning is 104 g, and the post-weaning average daily growth rate is 88 g. Fertility rates for ewes are from 4.5% to 7.0%, and average mortality rates from birth to weaning range from 10% to 18.2% (Elshazly and Youngs 2019).

6.5.2.12 Farafra

Origin and Distribution: The Farafra sheep (or Farafra Oasis sheep) (Fig. 6.16) is an indigenous Egyptian sheep found in the El-Farafra Oasis located in the desert region of Western Egypt, where average temperatures range between 39.5 °C and 41 °C and rainfall is low. It is thought to have originated by crossing Ossimi and Desert sheep breeds such as the Barki breed.

Physical Characteristics: The Farafra sheep breed has a body covered with white fleece (Elshazly and Youngs 2019). The head is brown in colour (Fig. 6.16), both sexes are polled, the tail is long and cylindrical, the average weight at weaning is 15 kg, ewe mean fertility rate is 90%, and the percentage of twin births ranges from 30% to 60% (Elshazly and Youngs 2019).

6.5.2.13 Dongola

Distribution: Synonyms for the Dongola breed include North Riverine wooled sheep and Riverain Wooled. It is a breed from a town in Northern Sudan, located on the banks of the River Nile, from where it gets its name. The breed is kept by the Sudanese Dongola Arabs, renowned as great merchants and travellers.

Physical Characteristics: The Dongola sheep are small sheep, with an average withers' height of 57–65 cm and an average adult weight of 13–32 kg. They are among the most fertile Sudanese sheep. The breed is covered with a top coat made up of long, sparse hairs and a woolly undercoat, similar to that found in the Karakul (discussed in Sect. 6.4.6.1) (Maisonneuve et Larose 1993).

6.5.3 Fat-Tailed Hair Sheep of Africa

The present-day African fat-tailed sheep are the most populous sheep with distribution across North Africa from Egypt to Algeria and from East Africa to Southern Africa. The fat-tailed sheep are divided into two subtypes; the first group comprises the East African fat-tailed breeds made up of the East African short-fat-tailed sheep and East African long fat-tailed sheep, and the second group comprises the African long-fat-tailed breeds (Rege et al. 1996).

The African long-legged sub-type of the African long fat-tailed is found mainly in arid and semi-arid zones of West Africa, Chad, central Africa and the eastern African country of South Sudan. These sheep are characterised by a convex nose, pendulous ears and very long legs that give the sheep a height of over 60 cm, an adaptation to the dry environments they are found in and the pastoralist lifestyle of their owners (Wilson 1991; Ryder 1983).

6.5.3.1 East African Fat-Tailed Sheep

Afar

Origin and Distribution: Synonyms for the Afar breed include Adal, Danakil and Elle. The Afar sheep is believed to have entered the African continent through the Horn of Africa from the Arabian peninsula (Muigai and Hanotte 2013). They are found mainly in northern Ethiopia, in the Afar State that borders Tigray, Amhara, eastern and western Harerghe and eastern Shoa regions of Oromia and are kept mainly by the Afar, Amhara and Tigray communities. The environment where these sheep are reared can be described as arid and semi-arid in mid-highland (1200–1900 m) to lowland regions (elevations less than 1000 m). The sheep are therefore reared in pastoral/agropastoral production systems (Gizaw et al. 2008a).

Physical Characteristics: The Afar is a medium sheep (Fig. 6.17), with mature weight

Fig. 6.12 Hamra Ewes in Mecheria City, Nâama Province, Algeria. (From (Djaout et al. 2017, licensed under CC-BY 4.0)

ranging from 30 to 35 kg. The sheep is characterised by a wide (16 ± 9 cm) fat-tail, which is long (19.1 ± cm) and has a slight 'S' shape that reaches below the hock (Gizaw et al. 2013). The large tail size qualifies its characterisation as a fat-rump sheep. However, it has been argued by Gizaw and others (Gizaw 2008) that they are fat-tailed sheep and ought to be classified as such. The body of the Afar sheep is covered with short hair fibre (3.2 ± 3 cm long) with a predominant cream or white colour (Figs. 6.17 and 6.18). The average measurements in females are: withers height—63.6 ± 8 cm; body length—58.3 ± 8 cm, heart girth—73.2 ± 6 cm and substernal height—35.6 ± 6 cm. The head is small, with a slightly convex profile in males, while females bear a straight profile. Pads of fat are observed on the nose and behind the poll. The ears are rudimentary in 80% of the animals; however, in a few animals, short ears of approximately 3.8 ± 4 cm are observed. Both sexes are polled, and about 5% of the animals bear toggles. The neck is short, often with a prominent dewlap. The chest is shallow and narrow. The tail head is higher than the withers (Wilson 1991; Gizaw 2008).

Adaptive and Special Genetic Characteristics: The Afar sheep breed is a hardy animal, adapted to the drought-prone arid and semi-arid regions of the Afar region of Ethiopia. Rainfall in these regions is erratic, with annual precipitation patterns ranging from 300 to 700 mm. The breed has developed adaptations to the harsh environmental conditions, including high temperatures, poor-quality feed and shortage of water. The breed has long legs that enable it to trek long distances in search of water.

Typical Production Systems and Production Characteristics: The Afar sheep is kept under pastoral and agropastoral systems mainly for meat production. The farmers, however, also milk the sheep and consume the milk at the household level. The sheep are milked an average of two times a day, producing an average of 224 ml of milk per day. The lactation average length is 3.8 months with a lactation yield of 25.5 litres per animal (Gizaw et al. 2013). The Afar lambs are once a year in traditional farming systems with an average litter size of between 1.03 and 1.14. Birth weight is 2.40 ± 0.6 kg and has an approximate weight of 11.9 ± 0.07 kg and 16.8 kg at three and 6 months, respectively. Adult males have a mature weight of 54 kg. The animals are kept for meat, milk and hides (DAGRIS 2007; Gizaw 2008). The agro-pastoralists and the pastoralists in the Afar region of Ethiopia mainly keep the Afar as a source of income and to provide milk for the household. A further reason for keeping the Afar aside meat is as a source of savings (Gebre et al. 2018). During emergencies, rams under the age of 6 months are the first choice for agro-pastoralists and pastoralists to take to the market for sale. Due to high demand, young rams were easily disposed of. Culling and sales of females are rarely practised, even for animals with unwanted coat colour, because most females in flocks are retained for breeding (Gebre et al. 2018).

Washera

Distribution, Classification and Population Statistics: The Washera breed (Fig. 6.19), which is also known as Agrew and Dangilla, is classified as an alpine short fat-tail sheep. They inhabit the West and East Gojam and Agew Awi zones of Amhara State in Ethiopia. They are approximately 1,227,200 head and inhabit terrain that can be described as wet and warm mid-highlands with altitudes of 1600–2000 m above sea level. They are kept by the Amhara and Agaw communities in (Gizaw et al. 2008a).

Physical Characteristics: Washera sheep have a short, fat tail (Fig. 6.19) with long ears that are approximately 10.6 ± 1 cm long. The body is large, with a withers height of 69.4 ± 3 cm for adult females and a body length of 66.7 ± 5 cm. The heart girth is 74.1 ± 6 cm and the substernal height is 38.6 ± 3 cm.

Adaptive and Special Genetic Characteristics: The Washera breed is tolerant to gastrointestinal helminth infections (Getachew et al. 2015).

Typical Production Systems and Production Characteristics: The Washera sheep are kept in the highlands by mixed crop-livestock farmers growing cereals. The animals are kept mainly for meat, manure and skin production. The production system is a semi-intensive to low-

input production system (Gizaw et al. 2008a). The sheep are prolific animals with an average litter size of 1.8. Adult females have an approximate weight of 32.8 ± 9 kg (Gizaw et al. 2008a).

Horro

Origin, Distribution, Classification and Population Statistics: Synonyms for the Horro breed (Fig. 6.20) include Abyssinian, Ethiopian, Bonga and Wollaga. The Horro breed is part of the Ethiopian group of sheep whose origin is believed to be Arabia via the Arabian Peninsula (Muigai and Hanotte 2013). The breed is classified as a long, fat-tailed hair breed. The sheep is the most widely distributed in the western and southern parts of Ethiopia, from the humid mid-highlands (1600 m) to the cool wet highlands (2991 m) in regions with high agricultural production potential. Relative extinction probabilities calculated for Horro indicate that the breed is relatively safe and not at risk of extinction. In 2008, 3,409,300 head were reported (Gizaw et al. 2008a). The breed is kept by the Oromo, Benishangul and Gambella communities found in Ethiopia.

Physical Characteristics: The Horro is a large breed (Fig. 6.20), with a withers height of 70.6 ± 6 cm and a substernal height of 38.1 ± 4 cm. The average female body length is 71.6 ± 6 cm with a heart girth of 76.9 ± 8 cm. Horro sheep have a long fat-tail that extends to below the hock (Fig. 6.20). The tail (average length 35.6 ± 6 cm, width 9.9 ± 3 cm) is straight in 51.4% of the population and coiled or twisted with a tapering at the end in 48.6% of the population. The majority of the population is brown-coloured or fawn, but black-, white- or fawn-coloured animals are also found. Ears are present and average 10.8 ± 2 cm. The body is covered with short, smooth hair that is on average 2.6 ± 1 cm. The females' belly is usually lighter in colour, especially in adult ewes, and both sexes are polled (Gizaw et al. 2008a).

Adaptive and Special Genetic Characteristics: The breed is well adapted to the regions where it is reared, producing good-quality mutton. Its habitat is located on the fringe of the trypanosome-infested environment, although the degree of trypanotolerance in Horro is not known (Gizaw et al. 2008a).

Typical Production Systems and Production Characteristics: The Horro breed is reared by sedentary mixed crop-livestock farmers mainly for meat (Edea et al. 2017). The greatest asset of this breed is its large size, which makes it popular among households that keep animals for meat. The live weights recorded in yearling males and females are 31.2 ± 1.70 kg and 26.5 ± 0.31 kg, respectively. Birth weights average 2.7–3.0 kg; weaning weights 11.8–13.5 kg; and 6-month weights are 15.4 kg–17.9 kg. The Horro breed is among the topmost prolific of the Ethiopian breeds, with a twinning rate of 1.29 ± 0.08. On average, households keep approximately 12 heads per household (Gizaw et al. 2008a).

Adilo

Distribution and Population Statistics: The Adilo sheep (Fig. 6.21) is described as a highland long fat-tailed sheep reared in the warm and wet mid-highland regions of the Southern State and northern Borena districts of Ethiopia. The sheep were approximately 407,000 heads in 2008 (Gizaw et al. 2008a).

Physical Characteristics: The Adilo is a large sheep (Fig. 6.21) that averages 28.1 ± 5 kg in mature weight, withers height of 65.5 ± 4 cm, substernal height of 35.8 ± 5 cm, body length of

Fig. 6.13 Beni Guil ram of Morocco. (From Bechchari 2009, published in an open-source report published by the Ministry of Agriculture, Kingdom of Morocco)

62.1 ± 5 cm and a heart girth of 71.8 ± 6 cm. It has a long and wide fat-tail that reaches the hocks, with an average length of 28.1 ± 1 cm and a width of 6.7 ± 3 cm. The males have short horns, while the majority of the ewes are polled, with 18.4% bearing horns. The predominant body colour is brown (94.3%) (Fig. 6.21), brown with white patches (32%), black (19%) and black with brown patches (9%). The body is covered with short hair (4.4 ± 2 cm long). The ears are long and average 11.7 ± 5 cm (Gizaw et al. 2008a).

Adaptive Characteristics: The Adilo sheep are adapted to the wet highlands of Ethiopia, which range between 1800 and 2000 m and produce high-quality mutton under these conditions.

Typical Production System and Production Characteristics: The Adilo sheep are reared by small-scale crop-livestock farmers on natural pastures and crop residues. Breeding is not controlled, and rams are left free in communal grazing areas. The sheep are kept in small flocks, which are tethered to a tree if they are one or two animals or left free during the day. During the cropping season, the animals are tethered in grazing areas. At night, they are housed in small enclosures. The average mean birth weight of Adilo lambs is 2.30 ± 0.03 kg and the mean average weight at 150 days is 15.7 ± 0.20 kg.

Bonga

Distribution and Population Statistics: The Bonga (Fig. 6.22) sheep, whose synonyms are Gesha and Menit, are native to the Kaffa region in Southwestern Ethiopia and in the Keffa, Sheka and Bench zones of the Southern State of Ethiopia (Gizaw et al. 2008a; Mamiru et al. 2018). Approximately 517,500 heads were reported in 2008 (Gizaw et al. 2008a).

Physical Characteristics: The Bonga sheep are large sheep (Fig. 6.22) with an average adult body weight of 34.2 ± 8 kg and a withers height of 66.7 ± 6 cm. The heart girth is 73.5 ± 7 cm, with a substernal height of 36.4 ± 4 cm. Bonga sheep has a long fat tail (25.9 ± 9 cm in length and 8.1 ± 3 cm in width) that hangs just at the hocks or below the hocks and tapers towards the end in a straight (67% of the population) or twisted manner (33% of the population). Most of the sheep are brown in colour (57.9%), though some white (10.5%) or black and white (0.9%) individuals can be found. The body is long (69.4 ± 5 cm) and is covered with short hair (~ 2.9 ± 1 cm in length). The ears are short (9.8 ± 2 cm in length), and both sexes are polled. Wattles are present in only 5.1% of the population (Gizaw et al. 2008a).

Adaptive Characteristics: The Bonga sheep are adapted to the humid mid-highland zone that ranges between 1200 m and 2500 m (Edea 2008).

Typical Production Systems, Husbandry Practices and Production Characteristics: The Bonga sheep are predominantly kept for meat production (Mamiru et al. 2018). The age at first lambing is 14.9 ± 3.1 months, with an average lambing interval of 8.9 ± 2.1 months. The average litter size is 1.40 with an average reproductive life span of 7.9 ± 3.1 year (Zewdu 2008).

Red Maasai

Distribution and Population Statistics: The Red Maasai sheep (Fig. 6.23) is commonly referred to as Maasai. It is predominantly owned by the Maasai ethnic group of East Africa, though in the past it was also kept by other Eastern African ethnic groups, such as the Nandi and the Abaluhya ethnic groups of Kenya (Wilson 1991). The Red Maasai sheep are distributed throughout northern Tanzania and south-central Kenya (Wilson 1991). Indiscriminate cross-breeding with breeds such as the Dorper has resulted in dilution of the breed. However, the breed has not been reported as threatened to date.

Physical Characteristics: The Red Maasai sheep is a large animal with an average height of 72 cm and 66 cm in males and females, respectively. The tail is long and fat, especially in sheep that are in good condition. The coat is red-brown with relatively long, smooth, coarse hair that can be up to 4 cm long (Fig. 6.23). Most animals have a woolly undercoat. The profile is convex in males and straight in females. The forehead is short and broad, and both sexes have horns that are up to 27 cm in length. The ears are semi-pendulous and are medium in length, 11–15 cm, although vestigial ears are present in approxi-

Fig. 6.14 A Saidi ram. (From Elshazly and Youngs 2019, licensed under CC-BY 4.0)

Fig. 6.15 A Saidi ewe. (From Elshazly and Youngs 2019, licensed under CC-BY 4.0)

mately 7% of the population. Toggles are present in approximately 15% of the population, and their size and position vary. The neck is short with a pronounced dewlap. The chest is narrow and shallow. The brisket is pronounced with a dewlap that carries fat. The average heart girth is 75.1 cm and 63.3 cm for males and females, respectively. The legs and back are short with a sloping croup (Wilson 1991; DAGRIS 2007).

Adaptive and Special Genetic Characteristics: The breed is adapted to arid and semi-arid regions. It is resistant to gastrointestinal nematodes and shows higher resistance than the Dorper, Blackhead Somali and Romney Marsh breeds (Wilson 1988; Baker et al. 2002). It is also resistant to bluetongue virus infection (Davies 1987) and has survived under high trypanosome challenge (Wilson 1991).

Typical Production Systems, Husbandry Practices and Production Characteristics: The sheep is raised within pastoral and agropastoral production systems and herded in mixed herds usually with goats and more recently with the Dorper breed. The animals move around during the day with their keepers and are contained within makeshift enclosures made from thorny shrubs. In these pastoral production systems, the flock structure is made up of 65% females and 31.5% males (Wilson 1991). First lambing is reported at 549 ± 112.1 days on a group ranch in Kenya, which is quite late and can be explained by the fact that the Maasai community uses leather aprons on males to control breeding. Multiple births are rare. The litter size is approximately 1.05 (n = 1009) in a group ranch in Kenya with an annual reproductive rate of 1.22. Birth weights are approximately 2.7 kg with an average daily gain of 73 g between 0 and 150 days in the pastoral production system. Mature weights are 21–47 kg and 32.55 ± 4.55 kg in males and females, respectively. The breed is kept mainly for meat, skin and lard (Wilson 1991).

6.5.3.2 African Long Fat-Tailed Sheep

The African long fat-tailed sheep comprises the East African long fat-tailed, which includes the Tanzanian long-tailed and Rwanda-Uruadi breeds, and the southern African long fat-tailed breeds, which comprise, among others, the Afrikander, Damara, Namaqua Afrikaner, Nguni, Tswana and Pedi breeds (Table 6.3) (Rege et al. 1996).

The Tanzanian Long-Tailed Sheep

Distribution: The Tanzanian long-tailed sheep are also known as Tanganyika long-legged, Ugogo, Gogo, Rwanda, Burundi and are widely distributed in the arid and semi-arid regions of Tanzania, Democratic Republic of Congo, Rwanda, Burundi and western Uganda.

Physical Characteristics: The Tanzanian long-tailed sheep are medium-sized sheep (Fig. 6.24) with an average adult weight of

Fig. 6.16 Farafra ram (left) and ewe (right) found in the El-Farafra Oasis, Western Egypt. (From Elshazly and Youngs 2019, licensed under CC-BY 4.0)

25–40 kg and an average height of 55 cm–65 cm. They have a thick, long, fat tail that tapers at the end. The head has a convex facial profile and is broad and short. Males have fat pads on the nose. Both males and females are polled. The ears are pendulous, hanging towards the front and are medium-sized in length. The body colour is black with white patches or brown and white patches. The body is covered with short or medium-length hair, with males having a mane and cape at the shoulders and a long apron of hair from the throat down the chest to the brisket (Wilson 1991).

Adaptive Characteristics: The Tanzanian long-tailed sheep are adapted to the dry conditions in which they are found. The thick, long, fat tail makes these sheep cope with seasons where there are critical food shortages (Devendra and McLeroy 1982).

Typical Production System and Production Characteristics: The sheep are maintained by small-scale crop-livestock farmers in mixed herds consisting of goats and cattle in an extensive livestock production system where the sheep are grazed in communal grazing land and kept in outdoor Kraal enclosures during the night (Nziku et al. 2016). The sheep are mainly reared for meat and income generation at the household level (Devendra and McLeroy 1982). Age at first lambing averaged 714 days on a station in Rwanda with an average lambing interval of 413 days (n = 863). Birth weights averaged 2.6 ± 0.02 kg on the station in Burundi (Wilson 1991).

Fig. 6.17 Afar ram in the Afar State of Ethiopia. (From Getachew 2008, through ILRI repository; CGSPACE, an open-source repository for Agricultural Research Output)

The Rwanda-Urudai

Origin, Distribution and Classification: The Rwanda-Urudai sheep are part of the East African long-fat tailed group. These sheep are distributed throughout Rwanda, Burundi, the Democratic Republic of Congo, southwestern Uganda and north-west Tanzania. In Rwanda, it is taboo to consume sheep meat, though the hides are used in the homesteads. This contributed to the rapid decline in the numbers of this breed and the breed is now at risk of extinction (Wilson 1991; Ndayambaje 2016).

Physical Characteristics: The Rwanda-Urudai sheep are small-bodied sheep, averaging 55–65 cm, with an adult average weight of 45 kg (male) and 35 kg (female). The head is convex, the forehead is broad and short. Males have pads

of fat behind the nose. Both sexes are polled. Ears are medium-sized and pendulous, with occasional vestigial ears. The tail is long and fat with a tapering end. The neck is strong and long. The chest is well-rounded with an average circumference of 72 cm. The legs are long and not very fleshy. The sheep are predominantly white and black in colour. The body is covered with long hair that is either stiff, wavy or fine. Males may have a mane and cape over the withers and shoulders and an apron of long hair from the throat down the chest to the brisket (Wilson 1991).

Typical Production System and Production Characteristics: The Rwanda-Urudai sheep are kept in mixed herds comprising cattle and sheep by crop-livestock farmers in high-altitude regions. The age of first lambing is 714 ± 18.4 days, and the lambing interval is 406 ± 7.5 days, with an average of 1.14 litter size in the traditional system and 1.43 on station in Rwanda. Multiple births are not common. For lifetime production, average parturitions are 2.29 in traditional systems, few ewes exceed 5 parturitions on station in 643 ewes (Wilson 1991). Average birth weights are 2.5 ± 0.56–2.6 ± 0.02 kg on station farms, with average weights of 6.3 kg and 31 kg in 30 days and 365 days, respectively (Wilson 1991).

The Ronderib Afrikaner

Origin, Distribution, Classification and Population Statistics: Like most indigenous South African sheep, the Afrikander originated from the Middle East and migrated into east Africa before migrating in a southerly direction with the KhoiKhoin people. The sheep first arrived in South Africa and eventually migrated to the west coast at the southernmost part of the African continent. Ronderib Afrikaner has a multicoloured coat and it is also known as Cape fat-tail, Afrikaner or Africaner. However, Cape Dutch farmers successively selected against the multicoloured coat, resulting in single-coloured animals that are prevalent today. The name 'Ronderib' is a reference to the cross-section of the ribs that are oval in shape (Bisschop et al. 1954). Two varieties are recognised, the Blinkhaar Ronderib Afrikaner, with soft shiny white hair and the Steekhaar Ronderib Afrikaner, which has coarse hair. The breed is distributed in South Africa and Namibia. The Steekhaar Ronderib Afrikaner is believed to be extinct (Epstein 1960; Snyman 2014a).

Physical Characteristics: Ronderib Afrikaner is a large fat-tailed sheep with adult live weights of 60–80 kg and 35–60 kg for rams and ewes, respectively (Epstein 1960; Ramsay et al. 2001). The fat tail is large, having a broad upper part with the same width as the rump hanging down to about three inches above the hocks, weighing between 2 and 3 kg and can go up to 5 kg (Snyman 2014a; Ramsay et al. 2001). The animals have large heads with a wide muzzle. The neck is long and narrow, with a prominent crown composed of fat and muscle tissue at the junction of the head and neck. The dewlap is well developed and extends to the brisket, which is prominent. The chest is well developed and capacious. The animal is tall with a withers height of 62.8 cm and 66.8 cm for rams and ewes, respectively and a height at hook bones of 69.4 cm and 68.4 cm for rams and ewes, respectively. The length of the body is 66.5 cm and 68.2 cm for rams and ewes, respectively. The heart girth is 99.7 cm and 89.2 cm for rams and ewes, respectively. The animals have long, thin legs. The convex forehead and Chaffron are separated by a slight depression

Fig. 6.19 Washera ram (left) and ewe (right) in the Amhara state in Ethiopia. (From Ferede et al. 2014, licensed under CC-BY 4.0)

in the interorbital region. The face is long, the eyes large, with ears that are fairly long, narrow, pointed and slightly pendulous. The rams have moderately sized horns that are spiral with distinct transverse wrinkles and grow backwards in a spiral that is close to the head. Only a small portion of the rams are polled and these animals have a more rounded head. Ewes are generally polled. The length of the rump is 23.5 cm and 22.6 cm in rams and ewes, respectively (Epstein 1960). The face and legs are covered with short, glossy, soft hair, and the body is covered with a glossy fleece of fine, smooth cream wool, approximately 3–6 cm long. The body is generally white, while the face is brown or reddish brown in colour (Epstein 1960; Snyman 2014a; Ramsay et al. 2001).

Adaptive and Special Genetic Characteristics: The Ronderib Afrikaner is a hardy sheep that can survive extremely adverse dry conditions. It produces a heavy carcass with flesh that has been described as stringy and coarse (Epstein 1960). It is well adapted to the dry, arid and semi-arid regions of southern Africa. It is also heat-tolerant and tolerant to parasites. The breed has long legs that enable it to walk long distances. It has a good foraging ability (Epstein 1960; Snyman 2014a).

Production Characteristics: The breed has high fertility, with the ram being active all year round. The ewes are good mothers. The age at first lambing is 8 months. The purebred animals are slow-growing and are best slaughtered at 10–12 months when they produce a good-grade carcass. The breed is kept for meat, which is high in fat. The fat-tail is usually in high demand for use as an additive in game meat and to make sausages. The Blinkhaar Ronderib Afrikaner has been used to develop several South African breeds, including Vandoor, Van Rooy and Afrino (Epstein 1960; Snyman 2014a).

Fig. 6.20 Horro ewe; Photo: ILRI/Apollo Habtamu. (Available on Flickr for free use under the Creative Commons Attribution Licence. (Image can be viewed here))

Damara

Origin, Distribution and Classification: The Damara breed has its origins in the Middle East and migrated first into east Africa and then migrated southwards into the southern African region, into present-day Namibia and Angola. Classified as an African long fat-tail sheep, these

sheep are native to the Damaraland region, a region known as 'The Koakoveld' in northern Namibia, where they were herded by the Himba and Tjimba ethnic groups for many years with little external influence. Himba have been hailed as one of the most successful pastoralist communities to date (Ramsay et al. 2001; Du Toit 2008). The breed is distributed in South Africa, Botswana, Namibia, Mozambique and Zimbabwe. The Damara breed is stable and thriving with several commercial farmers in South Africa and Namibia (Du Toit 2008).

Physical Characteristics: The Damara sheep are large animals with long legs. Both sexes have spiral horns that stand away from the head. The head has a strong profile, predominantly Roman-shaped. The tail is long and fat, reaching below the hock and gradually tapering down to a thin and pointed end. The eyes are large, bright and brown in colour. The teeth are hard and strong. The body is covered with short hair, though it grows longer during the winter and sheds during the warmer months. The body is long, oval and fairly deep. The body colour is predominantly brown, though white, black, grey and spotted multicoloured animals are also found. The top line is concave, dips to the neck, hollow, rises again, over the shoulder, dips into the back and rises again over well-developed loins. The legs are long, strong with well-shaped hooves. The dewlap is present and prominent in females (Snyman 2014b).

Adaptive and Special Genetic Characteristics: Damara sheep are adapted to the arid and semi-arid regions of southern Africa and can go for long periods without water. They can forage on grass, bush and shrub and survive and produce under very stressful natural conditions. The sheep have a high temperature tolerance and are very resistant to several sheep diseases, especially heartwater disease (Cowdriosis), parasites, intestinal worms, flies and blowflies. This enables the breed to be farmed where water and forage are scarce. The ewes have a strong maternal instinct and make good mothers, and low mortality rates of 2–4% are reported. The herd has high flocking instincts, with the mothers always gathering in a group that encircles the lambs, thus protecting them from wild animals. The sheep also easily adapt to other environments (Ramsay et al. 2001; Almeida 2011).

Production Characteristics: These sheep require minimum care and give high returns from the sale of meat and skins. The Damara sheep has a high fertility of 89–95%. The rams are active throughout the year, the females have a long productive life, and lambings occur on average every eight months (Du Toit 2008). The lambing intervals are short, and ewes can be mated throughout the year. The age at first lambing ranges between 14.6 and 17.3 months. Birth weights are 4–4.5 kg and 3–4.2 kg for males and females, respectively, with twinning rates reported at 35%. The weight at 100 days is 25 kg and 22 kg, with a mature weight of 60 kg and 45 kg for males and females, respectively. The weights reported at six and 12 months for both sexes are 32.3 kg and 46.6 kg. The Damara are kept for meat, the fat tail and

Fig. 6.21 Adilo ewe. (Photo: ILRI\Zerihun Sewunet) (Available on Flickr for free use under the Creative Commons Licence (Image can be viewed here))

skin (Schoeman 2000). The meat has a small amount of fat (1–2 mm) and is considered to be quite tasty, juicy with a lot of flavour. The tail is fatty, high in quality and is an ideal ingredient in sausage. The skins are used to produce very high-quality leather (Ramsay et al. 2001; Almeida 2011).

Namaqua Afrikaner

Origin, Distribution and Population Statistics: The Namaqua has its origins in the Middle East and migrated southwards into east Africa and then into southern Africa with the Khoisan people. The Namaqua breed is an endangered sheep breed with an estimate of only 2000 animals in 2014. Indiscriminate cross-breeding is the main reason why the animal is endangered. Two flocks of 100 ewes are currently being maintained in government-managed stations in South Africa (Snyman 2014c).

Physical Characteristics: The Namaqua breed is a tall animal with a narrow body and long, lean legs that enable it to walk long distances in search of water. The tail is fatty, weighing between 8 kg and 12 kg and stores up to 38% of the animal's fat. The tail is also long, reaching up to the hocks and bearing a distinctive twist at the end. The body is white with a black or red head. The hooves and horns are black. The body is covered with short, smooth and shiny hair that grows during the winter and sheds during the warmer months (Ramsay et al. 2001; Snyman 2014c).

Fig. 6.22 A Bonga ram. (Photo: ILRI/Apollo Habtamu) (available on Flickr for free use under the Creative Commons Licence (Image can be viewed here))

Adaptive and Special Genetic Characteristics: The Namaqua sheep is a hardy and prolific animal with high reproductive performance even when reared in severe and stressful environments. The Namaqua ewes can mobilise their fat reserves to wean heavy lambs even under extreme drought conditions. These ewes have excellent mothering instincts and defend their lambs fiercely against predators. The breed is adapted to extremely hot, dry desert conditions with intense infrared radiation during the day and extremely low temperatures during the night. Namaqua sheep are able to walk long distances in search of water and can reproduce under low-quality grazing conditions.

Production Characteristics: The Namaqua is a breed that requires little care. The average birth weights for rams and ewes, respectively, are 4.55 ± 0.33 kg and 4.27 ± 0.03 kg. The 100-day weaning weight is 26.1 ± 0.2 kg and 24.7 ± 0.2 kg for rams and ewes, respectively. The average weight gain from birth to 100 days is 215.4 ± 1.6 g/day and 204.8 ± 1.7 g/day, respectively, for rams and ewes, while between 100 days and 12 months, it is reported at 51.9 ± 0.2 kg (rams) and 44.0 ± 0.2 kg (ewes). The weight at 18 months is 58.7 ± 0.3 kg (rams) and 50.4 ± 0.03 kg (ewes). Conception rates of 86.0 ± 2.0% and fecundity rates of 156.4 ± 1.5% were recorded for a flock maintained on a private farm. The breed is farmed for its meat and skin. The skins produce high-quality leather, which is graded as Glover skins and is used to make high-value leather products such as jackets and gloves. The fat tail is prized in the meat processing industry, where it is used as a meat additive. The meat is, however, considered to be quite fatty and thus the carcass is not considered to be high-grade meat (Ramsay et al. 2001; Snyman et al. 1993).

Nguni

The Nguni sheep constitute four ecotypes, namely the Zulu, Pedi, Swazi and Landim sheep (Ryder 1983). They originated in the Middle East, from where they migrated into east Africa. They are believed to have migrated southwards

Fig. 6.23 Red Maasai sheep, Photo: ILRI. (Available on Flickr for free use under the Creative Commons Licence (Image can be viewed here))

into the southern African region with the Nguni people, following the eastern coastline of South Africa. The Nguni people separated and dispersed in different directions, each taking sheep along with them. One group, the Zulu people (after their leader 'Shaka Zulu'), settled in the plains of KwaZulu-Natal and then dispersed further south in search of suitable crop-growing areas (Ramsay et al. 2001). Their sheep are known as the Zulu sheep. Another group of sheep migrated with the Bapedi people to Sekhukhuneland, North East South Africa, in present-day Limpopo and Mpumalanga regions and became the present-day Pedi sheep (Ryder 1983). The third group of sheep migrated into present-day Eswatini (Swaziland) and are known as the Swazi breed (Kunene et al. 2007). Each of these four ecotypes is discussed below.

Zulu

Distribution and Population Statistics: The Zulu sheep are distributed throughout KwaZulu-Natal Province of South Africa, with the northern part of the province having larger numbers of sheep than the southern regions (Kunene et al. 2009; Mavule 2013). Despite its rich history and deep association with the Zulu, the breed is threatened with extinction (Kunene et al. 2009) due to replacement and indiscriminate cross-breeding with non-indigenous breeds (Mavule et al. 2013). Farmers' perceptions of its small size have led to perceptions that the breed is not favoured by consumers, leading to its threatened status (Mavule 2013).

Physical Characteristics: The Zulu sheep are medium- to small-bodied, average live weights for rams and ewes are 30.88 kg and 27.20 kg, respectively (Mavule et al. 2016). The average adult heart girth for rams and ewes is 73.62 cm and 71.75 cm, respectively. The sheep can have two types of tail phenotypes, a long, fat, carrot-shaped tail found in 39.5% of the population or a long, thin tail averaging 33.7 cm. Their body is multicoloured, with dark brown (26.6%) and dark brown with white patches (23.9%) being their predominant colour, followed by brown with white patches (17.5%) (Mavule et al. 2016). Solid brown, fawn, black and white coloured sheep are also found, though in smaller numbers (Mavule et al. 2016). The majority (73%) of the animals are polled, while only a small number (26.9%) are horned. The ears are medium-sized (28.55–30.09 cm), with a horizontal (70.3%) or dropping (28.9%) orientation. Vestigial ears were found in 19.7% of the population. The body is covered with wool.

Adaptive and Special Genetic Characteristics: The Zulu sheep are hardy and able to walk long distances in search of forage and water (Ramsay et al. 2001). They are highly adapted to the harsh climate that includes hot and humid conditions, resistant to gastrointestinal parasites and tick-borne diseases and have strong foraging ability (Ramsay et al. 2001; Nyamukanza et al. 2010).

Typical Production System and Production Characteristics: These sheep are kept by the Zulu people, who are mixed crop-livestock farmers (Kunene and Fossey 2006). The farmers also

Fig. 6.24 Tanzanian long fat-tailed sheep, Photo: ILRI/Cleaned VC. (Available on Flickr for free use under the Creative Commons Licence. (Image can be viewed here))

keep other livestock such as cattle, goats and chickens (Mavule et al. 2013). The sheep provide meat and meat products to the household and a source of income (Kunene and Fossey 2006). The sheep have low maintenance and are able to utilise low-grade farm by-products that are high in forage (Kunene et al. 2007).

Pedi

Distribution: The Pedi sheep are located in the Limpopo Province (Mpumalanga region) of South Africa.

Physical Characteristics: The Pedi sheep are small, with adult weights of 40 kg and 30 kg for rams and ewes, respectively. They are polled and have a long, thin, carrot-shaped tail that reaches between the hocks and hooves (Ryder 1983). Spiral tails are found in some animals, but this phenotype has been selected against by the breeders (Snyman 2014d). The body is small (withers height 62.94 ± 0.97 cm; thorax depth 32.22 ± 0.22 cm; body length 62.87 ± 0.32 cm) and shallow (heart girth 82.20 ± 0.34 cm) with long legs. The head is small (width 11.79 ± 0.15 cm), and the ears are also small (8.73 ± 0.25 cm). The rump is wide 16.42 ± 0.26 cm and long 20.98 ± 0.33 cm. The sheep are multicoloured, with most of the animals having a white body with a reddish-brown head due to selection for this phenotype (Snyman 2014d). Some animals' coat colours are brown, black with or without white or red/brown patches (Snyman 2014d).

Adaptive and Special Genetic Characteristics: The Pedi breed is tolerant to ticks and tick-borne diseases. Like the other Nguni sheep, the Pedi sheep are very hardy, rarely sick nor needing to be vaccinated. They are resistant to gastrointestinal helminths, Heartwater, Pulpy Kidney and Blue Tongue diseases. The sheep do not need to

be dewormed (Thaba Manzi Ranch 2021). They are also good foragers and are able to walk long distances in search of forage and water (Ramsay et al. 2001).

Typical Production Systems, Husbandry Practices and Production Characteristics: The Pedi sheep are reared for their meat, hides and fat tails. Their meat is tender and very tasty and lean (Ramsay et al. 2001). The fatty tail is valued for its additive value, especially in processed meats such as sausages (Thaba Manzi Ranch 2021). The hides produce leather that is of superior quality and grade. The Pedi sheep require very low maintenance but are slow-growing, taking up to 12 months to reach a slaughter weight of 18 kg (30 kg live weight) (Thaba Manzi Ranch 2021). The Pedi sheep are very fertile sheep, producing two lambs per year and are very good mothers that defend their lambs at all costs (Ramsay et al. 2001).

Swazi

Distribution: The Swazi sheep are predominantly found in rural Eswatini (Baker and Rege 1994; Lebbie and Ramsay 1999).

Physical Characteristics: The Swazi sheep are predominantly black, though multicoloured varieties with brown, reddish brown and white are found (Wilson 1991). The body is covered with hair that grows long along the back and rib cage (Wilson 1991). They are small sheep with an average body weight of 30.41 ± 0.41 kg. The other body measurements are 82.20 cm ± 0.34 (heart girth), 61.87 cm ± 0.36 (wither height), 30.28 cm ± 0.21 (thorax depth), 64.39 cm ± 0.31 (body length), 10.87 cm ± 0.14 (head width), 9.63 cm ± 0.24 (ear length), 15.51 cm ± 0.25 (rump width) and 21.73 cm ± 0.30 (rump length) (Gwala et al. 2015).

Adaptive and Special Genetic Characteristics: The Swazi sheep, like the Nguni, are adapted to the hot-humid and hot-dry climatic conditions of Eswatini. They are hardy and resistant to gastrointestinal parasites and local sheep diseases. They have developed a high tolerance for ticks and survive in environments that are endemic for heartwater, ticks and fleas (Ramsay et al. 2001).

Typical Production System: The sheep are kept in communal grazing lands by small-scale crop-livestock farmers (Ramsay et al. 2001).

Landim

Distribution: The Landim sheep are part of the Nguni group of sheep and are found in Mozambique, south of the Limpopo River (Wilson 1991).

Physical Characteristics: The Landim breed is a small animal with an adult withers height of 61–65 cm, adult body weight of 55 kg (males) and 35 kg (females) and adult heart girth of 80.7 cm ± 4.9. The sheep have a thorax depth of 30.19 ± 0.23 cm, a body length of 63.11 ± 0.32 cm and a rump width and length of 14.4 ± 0.25 cm and 21.96 ± 0.34 cm, respectively. The average head width is 12.23 ± 0.14 cm, with an average ear length of 10.13 ± 0.24 cm (Gwala et al. 2015). The breed has a long fat-tail (average 35.6 cm) reaching after the hocks but above the hooves. The body is covered with short (4 cm) coarse hair. The legs are long and thin. The head is convex, and the forehead is broad and short. Males have pads of fat on the face. The neck is long, and the back is long and straight. Both sexes are polled, with ears short (12.9 cm) and pendulous. Vestigial ears are present in 12% of the population (Wilson 1991).

Adaptive and Special Genetic Characteristics: The Landim breed is adapted to arid and semi-arid and the sub-humid tropics of Africa (Wilson 1991). They survive in dry tsetse-infested regions where zebu cattle cannot survive (McKinnon and Rocha 1985).

Typical Production System and Production Characteristics: The Landim breed is kept by small-scale crop-livestock farmers of Mozambique mainly for meat. The age at first lambing is approximately 805 ± 151.7 days, with a lambing interval of 412 ± 161.3 days. Twins are common and the litter size averages 1.41. The annual reproductive rate is 1.40 (Gwala et al. 2015).

Sabi

Distribution: The Sabi sheep are part of the African long-fat-tailed sheep and are the most

common sheep found in Zimbabwe. They are distributed in the arid and semi-arid regions of Zimbabwe.

Physical Characteristics: The Sabi sheep is a large animal with an average withers height of 60–70 cm, with adult weights of 40 kg in females and 50 kg in males. The head is strong, with a prominent forehead, convex in males and a poorly developed dewlap. They often have pads of fat behind the nostrils in males. The males can be horned (often with one twist) or polled, while females are often polled. Ears are short and horizontal or downward facing, the neck is short and thick, brisket is well developed, the chest is pinched and the withers are level with the tail head, legs are long and fleshy, the tail is long, often reaching the hocks and tapering to a point, and the tail is thin with no fat deposits. The body colour is dark or light brown, and black-coloured sheep are also found. The body is covered with short, coarse hair (Wilson 1991).

Adaptive and Special Genetic Characteristics: The Sabi breed is hardy and adapted to dry and arid regions with production rates higher than that of the Doper breed reared in the same environment (Matika 2001). The Sabi breed is resistant to gastrointestinal parasites (Matika et al. 2003; McKenzie 1987). When comparisons were made between the Sabi and Dorper breeds, the Sabi was found to be more resistant than the Dorper (Matika et al. 2003).

Typical Production Systems and Production Characteristics: The breed is kept in agropastoral, pastoral and ranching production systems for meat production. The Sabi breed is fertile, with a 19% twinning rate. The birth weights average 2.7 kg on a government farm, and lambs weigh 19.8 kg at 100 days, with an average daily weight gain of 130.7 ± 0.09 g for 0–140 days (Wilson 1991). The Sabi breed are slow-growing, and females conceive at 10 months with a body weight of approximately 18–20 kg (Devendra and McLeroy 1982), while males reach sexual maturity at 169 days with a weight of 21 kg (Arrowsmith and Ward 1983).

Tswana

Origin, Distribution, Classification and Population Statistics: The Tswana sheep are part of the Nguni group of sheep. Currently, they are found in Zimbabwe and Botswana. The breed is not at risk of extinction, with approximately 250,000 heads reported in Zimbabwe in 2018 (Molotsi et al. 2020).

Physical Characteristics: The Tswana sheep is a medium-sized sheep with an adult weight of 44.3 ± 2.6 kg in males. Height at withers is 45.0 ± 3.9 kg (males) and 63.2 ± 0.5 kg (females). The body's adult heart girth measures 65.1 cm ± 2.0 (males) and 65.8 cm ± 3.0 (females). The average body length is 57.7 ± 2.8 cm (male) and 57.0 ± 0.8 cm (females), with a shoulder width of 17.1 ± 1.1 cm (males) and 14.7 ± 0.3 cm (females). The ears are long (11.4 ± 0.8 cm (males) and 11.5 ± 0.2 cm (females)) and horizontal. The Tswana sheep have short horns with an average length of 0.5 cm (males) and 3.8 cm ± 2.3 (females) (Nsoso et al. 2004). The coat colour is predominantly white or white with multicoloured patches. The tail is short, fat, with an upward-pointing tip at the end. Wattles are present (Bolowe et al. 2021).

Adaptive Characteristics: The Tswana breed is a very hardy breed and able to produce in very dry regions.

Production Characteristics: Twin births are common, with a kidding rate of 1.21 per ewe and an average flock lambing rate of 80% on a government farm. The lambs have a weaning weight of 17 kg and an average weight of 26 kg in 12 months (Senyatso and Masilo 1996).

6.5.4 Fat-Tailed Coarse Wool Sheep of Africa

6.5.4.1 Menz

Origin and Distribution: The Menz sheep, also known as Legegora, Shoa, Abyssinian, or Ethiopian highland sheep, is believed to be a descendant of the Arabian sheep crossed with the narrow Bab-el-Mandeb straits located at the mouth of the Red Sea. It is classified as a short-fat-tailed sheep. It is one of the few woolled

sheep found in Ethiopia and is mainly kept by the Amhara community. It is widely distributed from the cool alpine mountainous climate in northern Ethiopia to the arid and semi-arid lands located in the lowland regions of Ethiopia (Fig. 6.25) (Tibbo et al. 2004).

Physical Characteristics: The Menz is a small sheep with short legs. The body is covered with a long fleece of coarse, wavy wool that is 8–11 cm long. The tail is fat with an approximate length of 17–23 cm and a width of 8–11 cm, the end of which is twisted and stops halfway to the hocks. Most are black or dark brown in colour, although light brown- and roan-coloured animals are also found (Fig. 6.25). White or brown spots on the head, neck and legs are common. The animals have an open face with a straight profile and short semi-pendulous ears that are 7–11 cm long. Approximately 12% of the population has rudimentary ears. The neck is short and thin. The back is short but straight. The rams have long twisted horns (Fig. 6.26) while ewes are mostly polled (Fig. 6.27). The body is compact and inclines forward slightly. Dewlap and wattles are absent. The average height at withers is 64–65 cm for males and 58–59 cm for females. The heart girth is 66–70 cm, and the average body length is 59–63 cm. Both the males and females have a nervous temperament (Gizaw et al. 2008a; Galall 1983).

Adaptive and Special Genetic Characteristics: The Menz sheep inhabit cool subalpine mountainous regions that are approximately 2500–3000 m above sea level. These regions have a severe cold climate, with temperatures ranging between 7.6 °C and 22.1 °C with strong cold winds and frosts mainly experienced between November and January. Functional analyses of the genes revealed that PPP1R12A, RELN, PARP2 and DNAH9 were involved in biological processes associated with adaptation to extreme altitudes, including influencing the development of the respiratory system and ensuring a smooth signalling pathway (Edea et al. 2019). The Menz sheep is tolerant to gastrointestinal helminth infections (Getachew et al. 2015).

Typical Production Systems and Production Characteristics: The Menz sheep are mainly kept to generate income for the households. This is mainly done through the sale of wool and meat in that order. Some of the meat is consumed at the household level and adjudged to be quite tasty. The sheep are also valued for manure production (Getachew et al. 2010). Flock sizes are generally small- to medium-sized, with up to 23 animals owned at the household level (Wilson 1991). The ewes reach first oestrus at around 350 ± 12 days at a mean weight of approximately 22–29 ± 0.6 kg and first lambing at 523 ± 13 days (Mukasa-Mugerwa and Lahlou-Kassi 1995) with a lambing interval of 255 days and 270 days in crop-livestock and pastoral production systems, respectively (Gizaw et al. 2013). Males reach sexual maturity at approximately 347 and 210 days in crop-livestock and pastoral production systems, respectively (Gizaw et al. 2013). Lambs recorded an average live weight at birth of 2.3 ± 0.1 kg and 9.8 ± 0.9 kg at weaning, with 14.3% being twins (Mukasa-Mugerwa and Lahlou-Kassi 1995).

6.5.4.2 Tikur

Origin, Distribution, Classification and Population Statistics: The Tikur, also known as Tekur, Tukur, or Tucur, like other Ethiopian sheep, is thought to have descended from Asia, entering Africa through the Horn of Africa (Muigai and Hanotte 2013). They are fat-tailed sheep kept by the Amhara community in the subalpine highland region of the North Wollo zone of Amhara state, Ethiopia (Gizaw et al. 2008a). The sheep numbers reported in 2008 were 525,300 heads, with a possibility that the numbers are declining due to decreased market demand for black-coloured sheep and sheep wool, resulting in selection against this coat colour in multicoloured, heterogenous populations (Gizaw et al. 2008a).

Physical Characteristics: The Tikur sheep is classified as a small fat-tail sheep with a woolly undercoat. The coat colour is predominantly black (60% of the population). The sheep has the following average measurements: body weight 25.4 ± 6 kg; withers height 64.1 ± 6 cm; body length 63.6 ± 6 cm; heart girth 69.7 ± 6 cm; substernal height 35.9 ± 5 cm. The ears are short,

6.8 ± 5 cm, and the tail measures 17.3 ± 6 cm long and 8.9 ± 3 cm wide. The coat is woolly with a fibre length of 7.4 ± 3 cm (Gizaw et al. 2008a; Ethiopia Sheep and Goat productivity Improvement Program (ESGPIP) 2008).

Adaptive Characteristics: The sheep is adapted to cold alpine and semi-alpine environmental conditions with feed shortages and is able to produce wool under these extreme conditions (Devendra and McLeroy 1982).

Typical Production System and Production Characteristics: The Tikur sheep is reared by small-scale mixed crop livestock farmers in barley growing regions of Ethiopia, an environment characterised as subalpine that is above 3000 m above sea level (Gizaw et al. 2008a). The sheep are reared under a traditional/free grazing management system (Weldeyesus 2020), mainly for meat and wool. The average litter size is 1.08 with a lamb survival rate of 95% (Devendra and McLeroy 1982). The average weaning age is 5.1 months (Mohammed et al. 2015).

6.5.4.3 Arsi-Bale

Origin, Distribution and Population Statistics: The Arsi-Bale sheep is believed to have its origins in the Arabian Peninsula (Muigai and Hanotte 2013). They are widely distributed in the cool, wet and highlands of eastern and south-central Ethiopia, ranging from 2000 to 3000 m. The climate in these regions ranges from semi-arid to sub-humid with annual rainfalls above 1500 mm. The sheep is reared by the Oromo communities, with 6,345,100 heads reported in 2008 (Gizaw et al. 2008a).

Physical Characteristics: The Arsi-Bale sheep is large in size with a withers height of 64.1 ± 6 cm and a substernal height of 35.3 ± 4 cm. The animals have a long, fat-tail, measuring 28.4 ± 6 cm in length and 6.2 ± 3 cm in width and have a twisted end. The heart girth is 73.3 ± 6 cm. The body is 62.3 ± 8 cm long and covered with coarse, wavy wool that is 4.2 ± 1 cm long. The colour is brown with white patches or black with white patches. Males and 52% of females are horned (Gizaw et al. 2008a).

Adaptive and Special Genetic Characteristics: These sheep inhabit the wet, cool highland areas with extreme temperatures. Candidate gene analyses showed that the Arsi-Bale sheep has genes that are associated with adaptations to extremely cold conditions (Edea et al. 2019) under which they are able to produce (Devendra and McLeroy 1982).

Typical Production Systems: The Arsi-Bale are raised in a range of production systems (agro-pastoral to agricultural and urban). Sheep are kept for meat, manure and hides. In the highland regions where farmers grow barley, the sheep are also kept in low semi-intensive production systems and are used for cereal cropping. In the perennial cash crop production system, the sheep are kept in low- to semi-intensive production systems where they are allowed to roam freely. The farmers in the wetter lowland regions keep large numbers of Arsi-Bale sheep while also practising cereal, sesame and cotton farming in semi-intensive low production systems (Devendra and McLeroy 1982; Gizaw et al. 2008a).

6.5.4.4 Wello

Location and Population Statistics: The Wello or Wollo sheep is an indigenous highland sheep found in the south Wollo administrative zone of Amhara state and is mainly reared by the Amhara community (Amare et al. 2018). A population size of 1,395,900 was reported in 2008 (Gizaw 2008).

Physical Characteristics: Wello sheep is characterised by a short fat tail, approximately 20.4 ± 6 cm in length, 7.2 ± 2 cm in width, which is twisted and turned up at the end. The animal has a small body with an average female body weight of 21.7 ± 5 kg, height, substernal height and length of 62.7 ± 5 cm, 34.3 ± 4 cm and 61.2 ± 5 cm, respectively. The heart girth for adult females is 67.9 ± 5 cm. The sheep has long hair (average 7.9 ± 4 cm in length) with a woolly undercoat. Most of the animals are either black, white or brown in colour, with white, black or brown patches. The males are horned (Gizaw et al. 2008a).

Adaptive and Special Genetic Characteristics: The breed performs well in dry regions and resists local diseases well (Ethiopia Sheep and Goat productivity Improvement Program

(ESGPIP) 2008). It is able to produce wool under extreme dry conditions (Ethiopia Sheep and Goat productivity Improvement Program (ESGPIP) 2008).

Typical Production Systems, Husbandry Practices and Production Characteristics: Sheep in this region are maintained in a mixed crop-livestock production system, with farmers releasing their animals to graze in communal and private grazing areas during the day, and at night they are kept in an enclosure together with the other livestock species owned at the household level (Amare et al. 2018). Breeding practice in the traditional systems is mainly random mating.

6.5.4.5 Farta

Origin, Distribution, Classification and Population Statistics: The Farta sheep (Figs. 6.28 and 6.29) is an indigenous sheep found in the South Wollo zone of Amahara State, Ethiopia, and is classified as a subalpine short-fat-tailed sheep. It is found in alpine and subalpine regions of Ethiopia, ranging between 2000 and 4000 m above sea level (Gizaw et al. 2008a). In 2008, 555,600 heads were reported. The Farta sheep is mainly reared in the cereal-growing regions in South Wollo of Amhara State in Ethiopia (Gizaw et al. 2008a).

Physical Characteristics: The tail is short, fat, measuring 22.9 ± 8 cm long and 9.6 ± 2 cm wide and reaches above the hocks. The average adult body weight is 28.3 ± 7 cm with a withers height of 67.9 ± 5 cm and a body length of 65.7 ± 7 cm. The average heart girth measures 72.0 ± 7 cm, and the substernal height is 37.3 ± 4 cm. The ears are long, measuring 9.9 ± 3 cm. The body is covered with a woolly undercoat with an average fibre length of 7.5 ± 3 cm. The body colour is predominantly white (37.5%) (Fig. 6.28), though brown (27.5%) and black with brown belly (15%), white and brown (Fig. 6.28), and brown and white patches are also found. Males are horned while females are polled (Fig. 6.29) (Gizaw et al. 2008a).

Adaptive Characteristics: The Farta sheep is reared in the highland regions of Ethiopia, where the environment is harsh and dry. Feed shortages are common. The breed is fully adapted to these conditions (Bimerow et al. 2011).

Typical Production System: The Farta breed is maintained in small-scale sheep production systems that can be further described as a low-input production system that involves mainly free range grazing (Gizaw et al. 2008a).

6.5.4.6 Semien

Distribution: The Semien sheep are found in the Simien Mountains region, which is rich in alpine mountainous ecology. The specific districts where the sheep are found include the South Gondar zone, Gondar zuria, Belesa and Dembia districts of Ethiopia and are reared by the Amhara community (Gizaw et al. 2008a; Melaku et al. 2019).

Physical Characteristics: The Simien sheep are the largest of the highland sheep. They have a short, fat tail measuring 12.8 ± 6 cm long and 9.6 ± 2 cm in width. The coat is woolly with a well-developed undercoat. The wool fibre is 8.2 ± 3 cm in length. The body colour is plain brown, plain white or brown with white patches or white with brown patches. The ears are medium in length, 8.3 ± 5 cm. The average body measurements are as follows: body weight −26.9 ± 4 kg, withers height −66.6 ± 6 cm, body length −64.7 ± 6 cm, heart girth −73.2 ± 6 cm, substernal height −35.9 ± 5 cm. The sheep are horned, with the males having long spiral horns and the females having short horns.

Adaptive Characteristics: The sheep are adapted to extremely cold, high mountainous regions (Melaku et al. 2019).

Typical Production Systems, Husbandry Practices and Production Characteristics: The Semien sheep are maintained in a smallholder production system where they graze on natural pastures in communal grazing areas where breeding is uncontrolled (Melaku et al. 2019). The Simien sheep are reared in barley-growing regions and are allowed to graze the crop stubble, thus clearing the farms (Melaku et al. 2019). Overgrazing of the sheep on the mountainous grasslands has resulted in their erosion, rendering them unproductive (Melaku et al. 2019).

6.5.4.7 Sekota

Distribution and Population Statistics: The Sekota sheep, also known as Tigray Highland and Abergelle, are found in the Central Zone of Tigray State in Ethiopia and are reared by Agew, Tigray and Amhara communities (Gizaw et al. 2008a).

Physical Characteristics: The Sekota sheep is a large sheep, with a long, fat tail, averaging 19.9 ± 8 cm long and 9.5 ± 3 cm wide. Sekota sheep have an average body weight of 26.6 ± 7 kg; withers height of 62.3 ± 6 cm; body length of 62.2 ± 6 cm; heart girth measurement of 69.9 ± 5 cm and substernal height of 35.9 ± 5 cm. The ears are medium in length, average of 8.3 ± 5 cm, semi-pendulous or rudimentary (Gizaw et al. 2008a).

Adaptive Characteristics: The Sekota sheep are adapted to the dry, lowland, semi-arid regions of Tigray state, which is 1500 metres above sea level, and are able to produce in these adverse conditions (Gizaw et al. 2008a).

Typical Production System and Production Characteristics: The Sekota sheep are reared in a lowland mixed crop-livestock production system in grasslands that are reported as degraded. The mean birth weight is 2.73 ± 0.06 kg, and the lambs weigh an average of 11.9 ± 0.21 kg at 3 months. The mean average weight gain from birth to weaning is 101 ± 2.66 gm. The breed is mainly kept for meat (Yiheyis et al. 2012).

6.5.4.8 Ossimi

Origin and Distribution: The Ossimi breed's origin is the Giza Governorate of Egypt, and it gets its name from a village near Cairo called Ossim. It is also known as Ausimi and Meraisi. It is the most popular sheep breed in the Nile and the Nile Delta. The breed is also found in the Middle East. The breed numbers are growing at the expense of the other local breeds and are considered to be the most productive breed in Middle Egypt. However, in Southern Egypt, it is not considered to be as productive.

Physical Characteristics: The Ossimi sheep has distinct white coarse wool which covers the entire body, although the neck, legs and abdomen have little wool. The head is brown or dark brown in colour and is convex in shape. The neck is short, often brown in colour or can have white patches. The sheep are medium-sized with a narrow, long body and long, thin legs. The males have curved, medium-sized horns that are black in colour with a downward-facing curvature, but females are polled. The average withers height is 75 cm and 72 cm for females and males, respectively. The average mature body weights are 45 kg (females) and 60 kg (males). The Ossimi have a fatty, cylindrical tail that weighs an average of 2.5–4.0% of the animal's weight (Elshazly and Youngs 2019).

Adaptive Characteristics: The Ossimi sheep are hardy and adapt easily to various environments found along the Nile Valley.

Typical Production Systems, Husbandry Practices and Production Characteristics: The Ossimi sheep is primarily kept for wool, which is mainly used in the carpet industry. The fleece weighs between 1.4 kg and 2.8 kg. The Ossimi is also a milk-producing sheep and has an average lactation length of 84 days and produces an average of 65 kg milk. The milk has an average fat content of 6.3%. The average daily weight gain is 100 g. The average mature carcass weight is 16 kg with an average dressing percentage of 46%. Average birth weights recorded for the breed are 3.2 and 2.9 kg for males and females, respectively. A twinning rate of 10–20% has been recorded with an average conception rate of 6.1%. The carcass produces good-quality meat, with most of the fat being concentrated around the tail region.

6.5.4.9 Barki

Origin, Distribution, Classification and Population Statistics: The Barki sheep (Figs. 6.30 and 6.31), often also called Desert sheep, are distributed in the coastal Mediterranean zone of Northern Africa. The Barki sheep gets its name from a province in Lybia known as Barka (Elshazly and Youngs 2019).

Physical Characteristics: The Barki sheep are small- to medium-sized (Figs. 6.30 and 6.31). The body is covered with white coarse wool, softer in texture when compared to the wool produced by the Ossimi or Rhamani sheep breeds.

The head is black, brown or white and bears small semi-pendulous ears. Males have horns which curve backwards (Fig. 6.30), while the females are polled (Fig. 6.31). The legs are long, thin and are covered with minimum wool, which enables the sheep to walk long distances. The sheep has a fatty tail, which is wide at the top and narrow at the bottom and often reaches the hocks.

6.5.5 Fat-Rumped Hair Sheep of Africa

The African fat-rump hair breeds are divided into the East African fat-rumped breeds that comprise the Blackhead Somali and the South African fat-rumped breeds, for example, the South African Blackhead Persian (Rege et al. 1996). They are widely distributed across the hot, dry desert regions of East Africa in Uganda, Somalia and South Africa. The Blackhead Persian of South Africa is documented to have arrived in 1868 on a ship from the Persian Gulf, with a high probability of the sheep having been loaded in Aden or off the Somali coastline (Mason and Maule 1960).

6.5.5.1 Blackhead Somali

Distribution: The Blackhead Somali (Fig. 6.32), also known as Blackhead Ogaden, is a fat-rumped tail sheep (Gizaw et al. 2008a) that is indigenous to the Ogaden area of the Somali region. It is widely distributed in the Horn of Africa in semi-arid and arid regions and is reared by pastoralists located in Ethiopia, Somalia and Kenya. There is a high demand for this breed in the Middle East, with live exports of sheep and goats from Somalia reported at 4.6 million in 2014 (FAO et al. 2017).

Physical Characteristics: Blackhead Somali sheep has a short-fat tail with a stumpy appendage, 14.7 ± 6 cm long and 14 ± 9 cm wide. The body is white in colour except for the neck and head that are black (Fig. 6.32) with an average body length of 59.9 ± 9 cm. The body is covered with short hair (4.0 ± 3 cm long). The weight for mature females is 27.9 ± 9 kg with a heart girth of 71.5 ± 6 cm. The animal is large, with a withers height of 63.3 ± 6 cm and a substernal height of 35.1 ± 6 cm. The sheep has a convex face, which is prominent in the males. The ears are outward and forward dropping and 9.6 ± 4 cm in length. Both sexes are polled, and the dewlap is well developed.

Adaptive and Special Genetic Characteristics: The Blackhead Somali sheep is a hardy sheep

Fig. 6.25 Indigenous Menz sheep herd in Amhara Region, Ethiopia; Photo: ICARDA\Getachew Mengistu. (Available on Flickr for free use under the Creative Commons Licence. (Image can be viewed here))

Fig. 6.26 Menz ram in Menz Area, Ethiopia. (From Ferede et al. 2014, licensed under CC-BY 4.0)

Fig. 6.27 Menz ewe in Menz Area, Ethiopia. (From Ferede et al. 2014, licensed under CC-BY 4.0)

that is well adapted to heat, feed and water shortages experienced in semi-arid and arid environments (Gizaw et al. 2008b). The breed is adapted to extreme conditions where they continue to produce all year round (Rocha et al. 1990).

Typical Production System and Production Characteristics: This breed is mainly reared for meat by pastoralists. The age at first lambing is reported at 666.73 days (DAGRIS 2007). The mean lambing interval of the Blackhead Somali reared in the Kenyan Maasai pastoral system is 312 days (Peacock 1996).

6.5.5.2 Blackhead Persian

Origin and Distribution: Synonyms for the breed include Persian and Swartkoppersie (Afrikaans). The Blackhead Persian sheep of South Africa has its origins in the Horn of Africa. This breed was founded from one ram and three ewes that were obtained from a shipwreck off the Cape coast in 1869. They have a white body with a black head, but animals with red heads are also common. Red speckled animals, together with blackheads, are still found in the population. Somali traders along the eastern coast are thought to have introduced more animals. Three distinct varieties are recognised: the Blackheaded Persian, the Redheaded Persian and the speckled (skilder) Persian (Ramsay et al. 2001). This breed has been used to develop the Dorper breed by crossing it with the Dorset Horn (which was developed by crossing Spanish and English breeds in the sixteenth century). The Black Head Persian is not at risk.

Physical Characteristics: The Blackhead Persian is a small- to medium-sized sheep whose body is covered with smooth white hair. The rump and base of the tail have fat deposits, giving rise to a stumpy fat rump. The head and neck are coloured black. The ears are long and pendulous, and both sexes are polled. The average mature weight of rams and ewes is 68 kg and 52 kg, respectively, while the birth weights are 2.6 kg and 2.55 kg for males and females, respectively (Ramsay et al. 2001).

Adaptive and Special Genetic Characteristics: The Blackhead Persian sheep is fertile, extremely hardy and well adapted to the arid and semi-arid climates in South Africa. The sheep is resistant to helminths. They are able to walk for long distances and survive for long periods without water.

Typical Production System and Production Characteristics: The Blackhead Persian sheep is mainly bred for meat under extensive veld conditions, although previously the fat stored in the tail region was highly valued for cooking. Although the body is covered with a mixture of wool and hair, they are not sheared. The age at first breeding is 7 months. The Blackhead Persian ewe have good mothering qualities, producing large quantities of milk and suckling their young for approximately 84 days. The ewe produces approximately 50 kg of milk during a lactation period. The milk is of good quality and contains 5.9 percent fat. The average litter size is 1.08. The lambs grow very fast and are ready for slaughtering at an

average of 4 months of age. The rams fare well in cross-breeding programmes. The breed is described as having an even temperament. It is fertile and usually gives lambs without complications. The fat tail is used as an additive to processed and game meats. The hide is used to produce high-quality leather that is known as Cape glover. The ewes are bred to Dorset Horn sheep to produce Dorper sheep breeds (Ramsay et al. 2001).

6.5.5.3 East African Blackhead Persian

Distribution and Classification: The East African Blackhead Persian is part of the fat-rumped hair sheep of Africa. It is found distributed in southern Uganda, west of Lake Victoria, regions around Mbarara in Uganda, northwestern parts of Uganda around Moroto and south and east into Sukumaland in Tanzania. The ecological region inhabited by the sheep can be described as semi-arid and sub-humid in medium- to low-altitude areas.

Physical Characteristics: The animal is small in size, with an adult female weight of 25 kg. The head has a finer shape when compared with other fat-tailed breeds, with a long neck and fat pads present on the nose and behind the ears. Both sexes are polled. The ears are short (5–8 cm), pendulous or vestigial. The chest can be described as pinched. The withers are level with the sacrum, or slightly lower. The back is short, straight or dipped. The brisket is well developed, but the dewlap is not very prominent except in very fatty sheep. The tail is prominent, with a large, fat tail. The body is white with a black head. The coat is short and coarse wool.

Typical Production Systems and Production Characteristics: The sheep is managed in pastoral and agropastoral production systems. Age at first lambing is 532 ± 8.1 days with a lambing interval of 255 days ±2.3. Twinning frequency is reported at 18%, with the sheep producing an average of 7 lambs in 5–6 years. The average birth weight is 2.5 ± 0.02 kg, and the average weight at 2 months is 10.1 ± 0.07 kg, while at 5 months it is 15.5 kg and 14.2 kg for males and females, respectively. The average daily weight gain between birth and 2 months is 123 g and 95 g for single births and multiple births, respectively.

6.5.6 Introduced Breeds

6.5.6.1 Karakul

Origin, Distribution and Population Statistics: The Karakul breed, also known as Astrakhan, is a fat-tailed fur sheep and is native to Central Asia and has its origins from the steppes of Turkistan (Mason 1996; Snyman 2014e). The Karakul were first imported into Namibia in 1907, with 12 sheep (2 rams and 10 ewes). Approximately 750 Karakul sheep were imported at the beginning of the 1900s (Wilson 1991; Ryder 1983; Snyman 2014e). The Karakul expanded rapidly in the 1930s, spreading into the surrounding regions of Namibia, South Africa, and Botswana, with a few reaching Angola (Viljoen 1981). By the 1970, it was the predominant breed in Namibia, with five million head constituting 95% of the Namibian flock, with exports of up to five million pelts out of South Africa and Namibia in 1979 (Rawlingson 1994). However, the African Karakul population has seen a decline in numbers as a result of various factors, including a rapid decline in Karakul stud breeders due to declining wool prices/demand for Swakara pelts and changing climatic conditions that have led to successive droughts (Snyman 2014e; Rawlingson 1994). The breed is found in South Africa, Botswana, Namibia, Mozambique and Angola. The population was estimated at 200,000 animals in Namibia and approximately 40,000 animals in South Africa. Total estimates for Africa are between 160,120 and 240,784 animals (Schoeman 2000; Molotsi et al. 2020; Snyman 2014e).

Physical Characteristics: The Karakul breed is a medium-sized sheep. The pelt is mainly black, but grey, white and brown are also found. The body is covered with a mixture of coarse and fine fibres that range in colour from black to grey. The tail is wide and fatty. The head is long and narrow, with slight indentations between the eyes. The ears are long and point downwards. The rams are predominantly horned, while the ewes are polled (Snyman 2014e).

Fig. 6.28 Farta ram in Farta District, Ethiopia. (From Ferede et al. 2014, licensed under CC-BY 4.0)

Fig. 6.29 Farta ewe in Farta District, Ethiopia. (From Ferede et al. 2014, licensed under CC-BY 4.0)

Adaptive Characteristics: The breed is well adapted to the semi-arid and arid areas and has thrived in the dry regions of southern Africa where it was introduced (Snyman 2014e).

Production Characteristics: The breed is kept for wool, pelt, meat (which is lean) and milk. The milk is creamy and used for butter and cheese production. The wool is used to make a large variety of wool and pelt products (Snyman 2014e).

6.5.6.2 South African Mutton Merino

Origin, Distribution, Classification and Population Statistics: The South African Mutton Merino, also known as German Mutton Merino, was first imported from Germany into South Africa in 1932. The goal was to develop a sheep breed that would utilise the winter pastures by having lambs born in autumn, rearing them quickly so that they could be marketed before the grazing dried up during the dry summer months. It is not a true landrace and has been developed through selection and used in the development of other South African breeds, namely Afrino, Dohne Merino, Dormer and Vandor. Although the current numbers of the South African Merino are not known, the breed is not threatened (Ramsay et al. 2001; Snyman 2014f).

Physical Characteristics: The South African Mutton Merino is a large animal with a mature weight of 125 kg and 70 kg for rams and ewes, respectively. The average birth weight is 4.1 kg and 3.8 kg for rams and ewes, respectively. The 100-day weight is 32 kg and 29 kg for rams and ewes, respectively. The breed produces good-quality wool with an average fibre diameter of 21–23 microns. The wool production averages at 4.5 kg and 3.4 kg per ram and ewe, respectively (Ramsay et al. 2001; Snyman 2014f).

Adaptive Characteristics: The South African Merino is adapted to the dry, arid and semi-arid regions. It also does well in regions that are not dry (Snyman 2014f).

Husbandry Practices and Production Characteristics: The South African Mutton Merino is kept for both mutton and wool. The wool provides a good source of income. The ewes have high fertility and good mothering ability and produce multiple births. The rams are suitable for cross-breeding. The breed grows fast and has a high feed conversion rate. The animals are non-selective when it comes to grazing. The carcass produced is of high quality, with exceptional conformation and tender meat. This breed has been used in the development of other breeds, such as the Dormer and Dohne Merino.

6.5.6.3 Barbados Blackbelly

Origin: Barbados Blackbelly is widely accepted as an African sheep breed. Although there can be little doubt that the Blackbelly has African ancestry, there is compelling historical evidence that

the Barbados Blackbelly, as a breed, originated and evolved on the island of Barbados, following the colonisation of Barbados by the English in 1627. The evidence reviewed supports the view that the Barbados Blackbelly evolved from crosses of African hair sheep and European woolled breeds. For Barbados Blackbelly, the parent stocks necessary for the evolution of a highly prolific, tropically adapted breed were established in Barbados in the first quarter-century of colonisation.

Physical Characteristics: Mature ram body weights range between 47.6 kg and 56.6 kg, while adult ewes weigh approximately 45 kg. The coat bears all shades of brown, tan or yellow, with deeply contrasting black underparts that extend down the inside of the legs. The animals bear black parts on the nose, forehead and on the inside of the ears. Rams have a neckpiece of thick hair, which extends down the neck to the brisket and may cover part of the shoulder in some animals. The head is medium-sized with good conformation down to the neck and body. Ears point forward from the side (not droopy). Both sexes are polled. The neck is medium in length, slender in comparison to the body size. Rams are heavier and have well-set shoulders. The body is fairly deep with well-sprung ribs. The back and loins are medium-sized, with deficient hindquarters that are very similar to what is observed in goats. The rump is quite steep from the hips to the pin bones, and the tail is set very low. The legs are fairly long and thin and are generally well set. When observed from a distance, the Barbados Blackbelly sheep resembles a small deer or antelope in appearance. The sheep are very active and lively and are alert at all times. Compared to the more recognised mutton sheep breeds, the Barbados Blackbelly sheep are less 'squatty' and are slower growing.

Adaptive and Special Genetic Characteristics: Barbados Blackbelly sheep has a rare attribute of adaptation to a wide range of environments. In cooler climates, they develop protective wool undercoats during the fall and winter that shed in the spring. Barbados Blackbelly is resistant to intestinal parasites.

Production Characteristics: Barbados Blackbelly ewes have high prolificacy due to high reproductive efficiency, which accounts for their average of two lambs per litter and an average lambing interval of 8–9 months. Average lambing rate ranges between 1.50 and 2.30 per ewe. Body weights of yearling ewes are variable due partly to the tendency to breed ewes that are less than 12 months old. However, most weigh between 36 kg and 40 kg. Carcass studies of 5- to 7-month-old rams sent to slaughter show that the Barbados Blackbelly breed has much less body fat compared to other sheep breeds. The flavour of the meat has been described as excellent and milder compared to other breeds. Estimated daily average gains from 5- to 7-month single rams range between 181 g and 204 g when fed on rations of alfalfa hay and wheat with mineral supplement. These gains are perhaps 60–70% of the normal expected gain for wool sheep on similar rations. Crosses of Barbados Blackbelly with the Dorset Horn and Suffolk have resulted in a pronounced increase in growth rates of progeny.

6.5.6.4 Bergui

Origin, Distribution and Population Statistics: The Bergui breed (Fig. 6.33), also known as La race ovine Queue Fine de l'Ouest, was introduced by the Romans (Trouette 1929), who were known to be great lovers of wool, in the fifth century from Taranto in Italy, where it exists to date (Snoussi 2003). It is found in Algeria and Tunisia, occupying the western regions of Tunisia. Their numbers in Tunisia increased steadily over the years, reaching 32% of Tunisian sheep breeds by 2013.

Physical Characteristics: It is a wool breed with a fine tail. The breed is taller than the Barbarine and it has a straight dorsal line and a long, thin tail (Fig. 6.33).

Typical Production System: The breed is reared for milk and meat in mainly extensive production systems (Khaldi et al. 2011).

6.5.6.5 Rahmani

Origin and Distribution: The Rhamany breed (Fig. 6.34), also known as Rahmany, originated in northern Syria and northern Turkey and was

Fig. 6.31 Barki ewe. (From Elshazly and Youngs 2019, licensed under CC-BY 4.0)

Fig. 6.30 Barki ram. (From Elshazly and Youngs 2019, licensed under CC-BY 4.0)

introduced into Egypt in the ninth century. The original stock is the Red Karman from Turkey. The breed is named after Rahmania, a village in the Beheira Governorate in the north of the Delta. The breed is distributed in the central and northern Egyptian delta regions.

Physical Characteristics: The breed is the largest of the Egyptian breeds and is characterised by its red wool. The animal has small ears. The males have large horns (Fig. 6.34) and the females are polled (Fig. 6.35). The average wither height is 43 cm for females and 47 cm for males. The average mature weight is 62 kg for males and 50 kg for females. The breed has a fat tail and often has no earlobes (Elshazly and Youngs 2019).

Adaptive and Special Genetic Characteristics: The breed is believed to have some resistance to gastrointestinal parasites.

Production Characteristics: The Rahmani is mainly reared for wool and milk production to a lesser degree. The wool produced is of high quality, often used in the manufacture of carpets. Mature animals produce an average of 3 kg wool. The average lactation period is 85 days, with an average production of 60 kg milk with 3.2% fat. The daily weight gain for the breed is 145 g with an average dressing percentage of 52%. The average birth weight for lambs is 1.2 kg for females and 1.22 kg for males, with a relatively high twinning rate. The animals breed all year round. The weaning weight is 18–21 kg; yearling weight is 38.6–42.2 kg; twinning rate is 12–40%; conception rate is 41.5–57.8%; and weaning rate is 74–78%.

6.5.7 Developed or Composite Sheep Breeds of Africa

Commercial composites are breeds that have been developed through the crossing of indigenous African sheep breeds with varying proportions of exotic breeds. Commercial farmers in Africa, who were mainly of European origin, considered the indigenous African breeds generally not adequate for commercial production systems geared mainly towards wool and meat export. As a result, they imported European breeds. However, these European breeds were poorly adapted to the dry and tropical African conditions and suffered seasonal weight loss, parasitism, diseases and were attacked by predators (Almeida 2011). In order to mitigate these challenges, European breeds were crossed with indigenous African breeds, mainly in South Africa, resulting in new composite breeds, namely Dorper, Afrino, Van Rooy, Vandor and Meatmaster (Ramsay et al. 2001; Almeida 2011).

6.5.7.1 Dorper

Origin and Distribution: Synonyms for the breed include White Dorper, Dorsian, Dorsie (Afrikaans). The need to produce a high-grade

Fig. 6.32 Blackhead Somali sheep in a livestock market in Somaliland, Photo: ILRI. (Available on Flickr for free use under the Creative Commons Licence (Image can be viewed here))

mutton sheep breed, able to withstand dry South African conditions and produce fast-growing lambs, led to the crossing of Dorset Horn rams and Blackhead Persian ewes between 1933 and 1946 at the Grootfontein Research Station (Milne 2000). The results were half-cross Dorset Horn x Blackhead Persian, from which selections were made to form the foundation flock for the current breed. The breed was formally recognised in 1950 when a breed society was established (Ramsay et al. 2001; Milne 2000). The breed's hardiness and ability to produce in extremely dry conditions led to its popularity and rapid spread (Marais and Schoeman 1990). It is currently widely distributed in South Africa, has spread to neighbouring countries of Namibia, Zimbabwe, Zambia, Angola and Botswana and has been exported to Kenya, Burundi, Malawi, Mauritius, Palestine, Saudi Arabia and Australia (Milne 2000). The current numbers are not known; however, in 1997, the South African flock was approximately seven million heads (South African Department of Agriculture 1997).

Dorper sheep were imported to Germany in 1995 at a time when the wool market was in decline because they did not need to be sheared. Australian Dorper breeders are currently exporting their animals to Vietnam and India. Additionally, the Dorper was crossed with the Damara, a South African fat-tailed breed, resulting in the Damper breed. Damper rams are crossed with Merino females to produce meat animals in Australia and then sold to the Middle East for slaughter (South African Department of Agriculture 1997).

Physical Characteristics: The Dorper breed is a large animal with a black head and white body. It has an average adult body weight of 52.84 ± 0.30 kg, an average withers height of 64.43 ± 0.32 cm and a heart girth of 84.23 ± 0.32 cm. The average body length is 71.14 ± 0.30 cm with a rear rump width of 20.71 ± 0.24 cm and a rump length of 24.29 ± 0.32 cm. The average thorax depth is 36.54 ± 0.21 cm. The ears are long with an average of 11.43 ± 0.023 cm. The head is large with a width of 13.83 ± 0.11 cm (Gwala et al. 2015). The body is covered with a mixture of wool and hair, while the bare parts of the body are covered with white hair; shearing is not necessary.

Adaptive and Special Genetic Characteristics: The breed is very well adapted to arid and semi-arid environments and is able to produce well in dry conditions. It is able to survive dehydration

and quickly replenishes its body weight when water becomes available (Degen and Kam 1992). The Dorper's thick skin offers protection against harsh weather conditions (Buvanendran and Adu 2021). It has a higher browsing ability when compared to Merino breeds (Du Toit 2008). The breed has high resistance to diseases, including fly strike and fleece rot, though it has been found to be resistant to gastrointestinal helminths (Baker et al. 1999, 2002).

Typical Production Systems and Production Characteristics: The Dorper breed is adapted for both veld and feedlot production (Ramsay et al. 2001). The breed matures early, with Dorset ewes reaching maturity at 213 days and a live weight of 39 kg, with an average first-time lambing at 346 days and overall high lamb survival rates (Greeff et al. 1988). The Dorper ewes make good mothers and produce a large quantity of milk, averaging 1.22 kg of milk per day over approximately 77 days (Bonsma 1944). Fifteen years of production data taken in an arid region of Kenya reported Dorper ewes had a twinning rate of 10%, lambing (fertility) rate of 78%, average birth weight of 3.6 kg and pre-weaning lamb growth and mortality rates of 178 kg per day and 14%, respectively (King'oku et al. 1975). The breed produces high-quality mutton that is described as tender and juicy (Ramsay et al. 2001). There is high demand for their skin, which is used to make high-quality leather products.

6.5.7.2 Afrino

Origin, Distribution and Population Statistics: The Afrino sheep is a dual-purpose meat and white wool-producing sheep found in the Southern Free, Eastern Cape and Northern Cape provinces of South Africa. It was developed in the late 1960s, specifically to meet the needs of commercial farmers who needed a sheep breed able to produce high-quality white wool similar to that of the Merino breed and, at the same time, produce high-grade mutton while being hardy and adapted to grazing in extensive production systems (Snyman 2014g). The result was the Afrino, which was developed from a combination of 25% Merino, 25% Ronderib Afrikaner and 50% South African Mutton Merino (Snyman 2014g). An Afrino breeders' society was established in 1980. The risk status of the breed is unknown. However, reported numbers in the period 1990–2018 are between 1000 and 3141 heads (Molotsi et al. 2020).

Physical Characteristics: The Afrino sheep is large, and its body is covered with white wool. The average mature weight is 80 kg (males) and 60 kg (females). The head is large, with strong upper and lower jaws and prominent nostrils, and the face is covered with soft cream wool. The average body length is 60–80 cm. The rams may have small horns while the ewes are polled. The chest is deep and wide, and the hindquarters are wide across the hips and pin bones. The legs are muscular and well-fleshed. The legs are of average length (Ramsay et al. 2001; Snyman 2014g; Afrino Sheep Breeders Society n.d.).

Adaptive and Special Genetic Characteristics: The breed is adapted to the arid and semi-arid veld and is able to produce in extremely harsh environments. The ewes make excellent mothers, leading to high survival lamb rates (Ramsay et al. 2001; Snyman 2014g).

Production Characteristics: The average age of first lambing is 10–17 months. Average birth weight is 4.9 kg and 4.6 kg for rams and ewes, respectively. The weaning weight at 120 days is 32 kg and 29.5 kg for rams and ewes, respectively, while corresponding weights at 9 months are 49 kg and 43.5 kg. The sheep are kept mainly for meat (80%) and wool (20%) production. The average carcass weight is 19.8 kg. The sheep produces Merino-type wool with an average diameter of between 18 and 22 microns. Ewes that raise lambs produce between 2.5 kg and 3 kg wool per year (Snyman 2014g; Afrino Sheep Breeders Society n.d.).

6.5.7.3 Van Rooy

Origin and Distribution: Synonyms for the breed include Van Rooy White Persian, Van Rooy Persie (Afrikans) and White Persian. This breed was developed in 1906 by a South African farmer known as JC van Rooy, who first mated a Ronderib Afrikaner ram to a French Merino *de Rambouillet* ewe. In order to improve carcass characteristics, he introduced a polled

Wensleydale ram. The breed is mainly reared in South Africa. The breed is not under threat and numbers are not known (Almeida 2011; Snyman 2014h).

Physical Characteristics: The Van Rooy is a medium- to large-framed animal with a predominant fat rump tail that has a huge oval from which a little tail hangs vertically. Both sexes are polled. They have a characteristic dewlap from the jaw to the brisket with a prominent chest and brisket. The body is covered with a mixture of hair and wool (Ramsay et al. 2001; Snyman 2014h).

Adaptive and Special Genetic Characteristics: The breed is adapted to the arid and semi-arid savannah, especially the dry north and northwestern Bushveld regions of South Africa around the Orange River and in Gauteng. It is heat and drought-tolerant and can cope with extreme hot and cold temperatures during the day and at night (Ramsay et al. 2001; Snyman 2014h).

Production Characteristics: The Van Rooy is a minimum care breed that is kept mainly for meat and skins. The breed is fertile and ewes can be mated throughout the year, making the breed suitable for accelerated lambing systems (Ramsay et al. 2001; Snyman 2014h).

6.5.7.4 Vandor

Origin, Distribution and Population Statistics: The Vandor sheep was developed by a South African farmer, Mr. CJ Van Vuuren, in 1944, when he crossed Van Rooy and Dorset Horn and later in 1958 with a German Merino in order to get a composite that would produce high-quality wool and meat. A Vandor breeders' society was established in 1968 (Ramsay et al. 2001; Almeida 2011). Presently, the breed is found in central and western South Africa.

Physical Characteristics: The Vandor is a large animal with an average weight of 100 kg for rams and 90 kg for ewes. It has a distinct face with large ears. The body colour is mainly white. The body is covered with wool.

Adaptive and Special Genetic Characteristics: It is especially adapted to the northern Cape Province of South Africa, where the natural environment consists of grassveld and busveld (Ramsay et al. 2001).

Production Characteristics: The Vandor rams are fertile (2 rams per 100 ewes), and in normal conditions, the lambing rate is 150%. The lambs are born small but grow at a very fast rate of 300–400 g per day. The ewes have good mothering instincts, resulting in low mortalities. The rams weigh an average of 40–45 kg in 100–120 days. The sheep are kept for meat and wool production (Ramsay et al. 2001; Snyman 2014h).

6.5.7.5 Meatmaster

Origin: The Meatmaster is a composite breed that was developed in South Africa to survive the harsh, dry, arid and semi-arid environments and produce with low inputs and minimum care. The breed was the result of crossing Damara with several sheep breeds that included Ile de France, Van Rooy, South African Merino, Dorper, Namaqua and Ronderib (Peters et al. 2010).

Physical Characteristics: The breed is small- to medium-framed with a mature weight of 60–90 kg (rams) and 35–50 kg (ewes). The legs are well-placed, enabling it to walk long distances. Both sexes are polled. The body is multicoloured and covered with short shiny hair. The tail is long, thin and carrot-shaped and reaches the hock.

Adaptive and Special Genetic Characteristics: The Meatmaster is adapted to bushveld and savannah environments. It is tick-resistant and tolerant of tick diseases (Ramsay et al. 2001).

Typical Production System and Production Characteristics: The Meatmaster is reared mainly in an extensive production system. The breed matures early, lambs easily and the ewes make excellent mothers, resulting in low mortality rates. Birth weights average 3.2 kg and 2.8 kg for rams and ewes, respectively. The 100-day weaning weight is 27 kg and the animals weigh an average of 47 kg at 270 days. The adult weaning weight is 185 kg for males (Ramsay et al. 2001; Snyman 2014h).

6.5.7.6 Dohne Merino

Origin and Distribution: Synonyms for the Dohne Merino include Dohne and El Dohne Merino. Dohne Merino sheep was developed at

the Dohne Agricultural Research Station in Eastern Cape, South Africa (Snyman 2014i). The goal was to develop a hardy sheep able to produce mutton and wool in the harsh Sourveld environment. The Dohne Merino was developed by crossing a local merino with the South African Mutton Merino. Presently, the sheep are farmed in the Eastern Cape, Free State and Western Cape Provinces of South Africa and are also distributed in Namibia. The total number of Dohne Merino sheep is not known (Snyman 2014i).

Physical Characteristics: The Dohne Merino sheep are medium- to large-sized animals with an average live body weight of 80–100 kg (rams) and 50–65 kg (ewes). The coat colour is white and is covered with white wool. The Dohne Merino sheep are polled.

Adaptive Characteristics: The Dohne Merino sheep are hardy and well-adapted to the arid and semi-arid environments.

Typical Production Systems and Production Characteristics: The Dohne are suitable for both extensive and intensive production systems. Merino is a dual-purpose sheep that produces a high-quality carcass. The lambs do not accumulate fat at an early age, and hence, they can be marketed at a later stage. The breed has good fertility, producing lambs with a birth weight of 5.2 kg and 4.9 kg for rams and ewes, respectively. The lambs have a weight of 29.9 kg (rams), 31.1 kg (ewes) at 100 days, 46.3 kg (rams), 37.8 kg (ewes) at 8 months and 60.3 kg (rams), 48.6 kg (ewes) at 12 months. Dohne produces a very high-quality wool with an average fleece weight of 3–5.5 kg with a fibre diameter of 17.21 micron (Ramsay et al. 2001).

6.5.7.7 Dormer

Origin and Distribution: The Dormer breed was developed from crossing Dorset Horn rams and German Merino ewes in 1927. The name Dormer comes from an abbreviation of Dorset-Merino (Dormer Sheep Breeders' Society of South Africa 2022). The goal was to develop a mutton breed that could adapt to the cold and rainy winter conditions experienced in the Western Cape Province of South Africa. A Dormer Breed Society was established in 1965, and the breed was formally recognised in 1970. Presently, it is widely distributed in Gauteng and the Free States of South Africa (Ramsay et al. 2001; Snyman 2014j).

Physical Characteristics: The Dormer is a mutton sheep breed whose body is muscular and covered with white wool. The average adult weight is 75 kg. Both sexes are hornless, with a smooth body and good meat conformation.

Adaptive and Special Genetic Characteristics: The Dormer is adapted to temperate climates and does well in extreme cold and rainy conditions. It is also resistant to the Muellerius lungworm.

Typical Production System and Production Characteristics: The Dormer breed is raised in natural and planted pastures under an extensive production system for meat and wool. The lambs have a good feed conversion rate. The rams can be used in cross-breeding programmes to improve meat production. The breed is very fertile, and multiple births occur frequently. Lambs are born small but grow very rapidly. Birth weights average 3.9 kg and a weaning weight of 29 kg. The age at first lambing is 18 months. The breed matures early and is ready for the market after 3 months, with a live weight of 38.57 kg (rams) and 34.57 kg (ewes) and a carcass weight of 16–22 kg. The sheep produce fleece with an average weight of 3.5–5 kg with a diameter of 27 microns. The wool is strong, free of kemp and coloured fibres. The breed qualities make it a favourite choice of sires used in cross-breeding (Du Toit 2008; Sagne 1950). The efficiency of the Dormer has improved markedly, especially over the past decade, mainly due to performance testing that is compulsory for all South African breeders (Dormer Sheep Breeders' Society of South Africa 2022).

6.5.7.8 Tâadmith

Origin, Distribution and Population Statistics: The Tâadmith breed (Fig. 6.36) originated from a cross between the Eastern Merino and an indigenous breed from the Djelfa region of Algeria (Jores D'Arces 1947; Sagne 1950). The breed was developed in the 1860s at a national research station at Taâdmit, hence its name. The main objective of its development was to improve the

Fig. 6.33 Bergui ewes. (Queue Fine de l'Ouest) (Tozeur). (From Khaldi et al. 2011, licensed under CC-BY 4.0)

Fig. 6.34 Rahmani ram. (From Elshazly and Youngs 2019, licensed under CC-BY 4.0)

Fig. 6.35 Rahmani ewe. (From Elshazly and Youngs 2019, licensed under CC-BY 4.0)

wool quality of the Ouled-Djellal breed (Chellig 1992). The Tâadmit breed has a wide distribution in the central Algerian steppes. Currently, there are only a few hundred animals at the Djelfa Wilaya, especially in the Taâdmit region, due to gradual replacement by the Ouled-Djellal breed. A nucleus herd is currently being maintained at the Institut National de la Recherche Agronomique Research Station at Hmadna (Wilaya of Relizane).

Physical Characteristics: The Tâadmith breed is characterised by a white head with a hooked profile and a long body, with males having large and bulky horns (Fig. 6.36). The animal is leggy, the fleece is extended, covering the forehead, sometimes extending down to the hocks. The wool is superfine to fine. The tail is long and thin.

6.5.7.9 Noire de Thibar

Origin and Distribution: Noire de Thibar (Fig. 6.37) is a Tunisian breed distributed in the basins of Medjerda and Béja. It is a composite breed developed by a monk from the Netherlands called Novat, in the wet and rainy northwestern region of Tunisia. He began the development of this breed in 1908 through the reciprocal crossing of Merinos d'Arles from southern France with the Algerian thin-tail breed (Queue Fine de l'Ouest) (Khaldi 1984). The goal was to produce animals with a uniform black colour that were naturally able to avoid consuming the poisonous St Johnswort (*Hypericum perfoliatum*) plant. In 1945, the breed was officially recognised, and a flock book opened under the name Race ovine Noire de Thibar, where approximately 3.5% of Tunisian sheep livestock are recorded (Chalh et al. 2007).

Physical Characteristics: The Noire de Thibar breed has a uniform black coat (Fig. 6.37), a cylindrical body and a good conformation. The head of the animal is black and has an elongated, concave shape. The sheep are polled in both sexes. According to Mason (1967), rams have a mature average weight of 80–90 kg and a mature height of 60–65 cm. The skin and mucous membranes are pigmented. The entire body is covered with a medium to fine fleece, which weighs 4–5 kg for rams and 2–3 kg for ewes. The skin and mucous membranes are black in colour, leaving only the head, throat, inner side of the tail and perineum exposed (Meyer et al. 2015).

Production Characteristics: The breed has a prolificacy rate of 130–134% with a fertility rate of 68–88% (Djemali et al. 1995). The seasonal anoestrus has been reported to be less among the Tunisian sheep breeds (Gouhis 1989), therefore allowing the breeders the opportunity to adapt their breeding to any season.

6.5.7.10 Sicilo Sarde

Origin, Distribution and Population Statistics: The Sicilo Sarde (Fig. 6.38), also known as Sicilian-Sardinian, is a composite breed developed from crossing an exotic Sardinian and Sicilian sheep. The original stocks of Sardinian and Sicilian sheep were introduced into Tunisia by Italian settlers before the 1900s. By 1949, there were 40,000 Sicilo Sarde sheep in the Tunisian districts of Mateur, Bizerta, Beja, Tunis and Grombalia. The Sicilian sheep had greater influence on the composite Tunisian milk sheep until further large importations of the Sardinian sheep were made in 1948. As a consequence of this, the Sicilio sheep are also known as Sicilian-Sardinian (Mason 1967).

The Sicilo Sarde sheep was not threatened until the 1990s. Since then, the numbers of this breed have fallen sharply from 219,000 heads to 37,000, 20,000 and 8500 heads recorded in the years 1995, 2005 and 2000, respectively (Ouhichi 2014). These sheep are currently being maintained in government-owned farms and private breeders, especially around the Beja region of Tunisia. The breed enjoys considerable socio-economic interest for rural Tunisia and has been prioritised for conservation.

Physical Characteristics: The Sicilo Sarde breed is a medium breed with a height at withers of 70–80 cm, and average adult weights of 45 kg and 65–75 kg for female and male, respectively. The coat colour is variable with white (Fig. 6.38), black or spotted animals. The fleece shape is heterogeneous and is described as jarred. The head is elongated with a straight face profile, which bears a slight curvature, and the muzzle is straight. The Sicilo Sarde sheep has a long, thin tail, and its legs are long and thin. Males have longer horns than females. The neck is long, and the ears are small and horizontal. The rump is long and the abdomen rounded (Rafik et al. 2018). The udder is well developed with straight teats (Khaldi and Farid 1981).

Typical Production Systems and Production Characteristics: The Sicilo Sarde breed is reared mainly for milk and meat under semi-intensive and extensive production systems. The semi-intensive production system is used in government farms and by private large-scale farmers with large flock sizes of between 200 and 300 ewes. The Sicilo Sarde is raised on pasture consisting of natural rangelands, stubble and barley, supplemented with hay, straw and concentrates during the dry periods or when animals are lactating (Rouissi et al. 2001).

In the extensive production system, the animals are reared under free-range grazing of pastures with high supplementation with concentrates (Rekik et al. 2005). Natural matings occur during the spring, which results in most lambings occurring between August and November and peaking between September and October (Djemali et al. 1995; Rouissi et al. 2001).

The Sicilo Sarde sheep is milked for household consumption. The milk is also used to make cheese. The cheese industry has, however, grown and has evolved into a traditional cottage industry, making specialised cheeses using milk from this breed (Khaldi and Farid 1981).

6.5.7.11 Sidi Tabet Cross

Origin, Physical and Production Characteristics: The Sidi Tabet Cross is a composite of Portuguese

Black Merino and Thibar breeds. The breed has a black coat and is polled in both sexes. It is specifically reared for wool production. The wool produced is of medium type (DAD-IS n.d.).

6.5.7.12 Sohagi

Distribution: The Sohagi sheep breed is widely distributed in the Egyptian Governorate of Sohag in southern Egypt.

Physical Characteristics: The body is covered with white wool. The Sohagi has a small head, covered with dark brown wool, with creamy black rings around the eyes. The neck is long, and the animal has long legs. The rams are horned, but females are polled (Elshazly and Youngs 2019).

6.6 Current Status of Sheep Diversity in Africa

6.6.1 Morpho-Biometric Studies and Population Characterisation

Morphological traits are important tools in livestock population characterisation. Furthermore, morphological characters are used by farmers as an indicator of the growth and reproduction performance of their animals. Traits such as the heart girth and wither height measurements are good growth indicators, and measuring the scrotal circumference gives a good indication of ram fertility, hence an indication of how a ram's daughters would perform reproductively (Portes et al. 2018). However, the use of morphological traits is often misunderstood and may be erroneously linked to practices that do not conform to cultural traditions, including superstition.

Morpho-biometric traits are therefore important tools in the characterisation of sheep populations and are complementary to the molecular markers used in population genetic diversity studies. African sheep breeds have been largely characterised using morphological characters such as rump width, rump length, tail length, wither height, heart girth, paunch girth, rump height, ear length, foreleg length, rear-leg length, body length, shoulder width, neck circumference, head length, head width, horn length and hock length and also the size of udder and quality of wool, amongst others.

These morphometric characters have been used to characterise the Nigerian Yankasa, Balami, Uda, and West African Dwarf sheep (WAD) breeds (Yunusa et al. 2013) where the results showed that the tail length was the most discriminating trait in the four populations, and the longest genetic distance was found between WAD and Uda sheep, while the closest breeds were Balami and Uda (Yunusa et al. 2013). A morphometric study of WAD sheep in Guinea Bissau showed phenotypic diversity in the studied population and three genetic groups, namely, large, intermediate and small (Dayo et al. 2022).

Similarly, Belharfi et al (Belharfi et al. 2017a). used 13 biometric traits to characterise six sheep breeds from western Algeria, namely, the Ouled Djellal, Hamra, Barbarine, Srandi, Daraa and Tazegzawt breeds, and the results showed distinct differences between males and females. Principal component analyses (PCA) of the measurements revealed three distinct clades of sheep, with one clade representing most of the breeds, an indication that the sheep breeds from this region have undergone dilution due to a high rate of gene flow between breeds. These results were later confirmed using genome-wide analysis (Gaouar et al. 2016).

Morphometric measurements analysed from 280 adult WAD sheep (77 males, 203 females) from the Sudano-Guinean zone of Cameroon showed high variability with distinct characteristics that can be used to distinguish the sheep (Deribe et al. 2021). Three genetic types with high intra-genetic variability clustered into two sub-groups of the local sheep population. The study concluded that selection is the most appropriate method to improve the sheep population.

A total of 22 phenotypic measurements taken from 288 Blackbelly sheep from three Central African countries, Cameroun, Congo Brazzaville and Gabon, revealed phenotypic dimorphism between the Blackbelly sheep populations in the three countries, with the tallest and heaviest animals from Congo Brazzaville (head

width = 62.217 ± 5.288 cm and body weight = 27.44 ± 6.08 kg), the longest from Gabon (TBL = 84.69 ± 8.70) while the largest were from Cameroon (CW = 15.01 ± 2.531 and rump width = 14.716 ± 2.351) (Meka et al. 2021). Further analyses using PCA revealed that six components could account for 73.1% of the observed variability in sheep body measurements. The study revealed a perfect correlation between the thoracic circumference and body weight, suggesting that the thoracic circumference could be used as an indirect indicator of body weight (Meka et al. 2021).

The morphological diversity of three fat-tailed and three thin-tailed indigenous sheep breeds of Ethiopia was determined based on live body weight and linear body measurements and revealed significant variations between breeds (Deribe et al. 2021). Multivariate analyses clustered the studied sheep breeds into distinct populations, with Mahalanobis distance showing significant differences between breeds.

Mavule and others (2016) examined eight Zulu sheep populations in KwaZulu-Natal sampled from Empangeni, Escourt, Eshowe, Jozini, Msinga, Mtubatuba, Nongoma and Nqutu rural communities, with findings that dark-brown coat colour, either in solid form or white patched, was most frequent. Analyses of linear body measurements and qualitative traits showed significant variations, with an indication that sheep from Nqutu had the highest estimates in most morphometric variables, while sheep from Empangeni had the lowest. Discriminant analysis identified rump width, head width, heart girth, thorax depth and tail length as the most distinguishing variables amongst sheep populations. Hierarchical cluster analysis revealed two major groups, one formed by populations from Empangeni, Mtubatuba and Nongoma, and the other by Jozini, Msinga and Eshowe populations. Estcourt and Nqutu were separated from these groups as individual entities. About 62% of individual sheep could be correctly identified with populations from which they were sampled. Nqutu had the highest percentage (88.9%) of correct assignments, whilst Mtubatuba had the lowest (46.7%). High assignment errors were ascribed to gene flow between sheep populations.

Udder measurements have also been effectively used to characterise sheep breeds. James et al (2009). evaluated udder and teat morphometrics, including udder and teat length, width, circumference, distances between teats, udder and teat shape of 143 extensively managed WAD sheep in southwestern Nigeria and reported that age, pregnancy and lactation status greatly influenced the teat length and udder circumference. Udder and teat dimensions significantly increase with age, while the smallest udder and teat dimensions were found in lactating and dry or non-lactating animals.

Analyses of sheep wool quality and dimensions undertaken in western Algeria on a total of 60 sheep sampled from the Ouled Djellal, Hamra, Barbarine, Srandi, Daraa and Rembi breeds by Belharfi et al. (2017b). showed that sex did not affect wool finesse in the breeds. The study also reported significant differences in the average wool fibre diameter among the breeds studied.

6.6.2 Biochemical Characterisation of African Sheep

The use of protein polymorphisms allowed for the characterisation of livestock species before the advent of molecular genomics. The technique uses the principle of separating proteins according to their electric charge and molecular weight.

Due to the degeneration of the genetic code, approximately three out of four mutations can cause an amino acid to be substituted for another during protein synthesis. In addition, only a third of these substitutions, on average, can change the net charge of the protein and are therefore detectable by electrophoresis. This, therefore, makes it possible to detect at the protein level about a quarter of the mutations existing in the coding part of the corresponding gene (Grosclaude 1988). The immunological and biochemical characters have a fairly simple mode of hereditary transmission that conforms to the laws of Mendelian genetics. Some of the best-known traits used for characterisation are blood groups

Fig. 6.36 Taâdmit ram in Djelfa, Taâdmit. (From Djaout et al. 2017, licensed under CC-BY 4.0)

and blood proteins. They are genetically independent of each other; their analysis makes it possible to better characterise the hereditary attributes of breeds compared to studies based on morphological characters.

Eight polymorphic loci were used to characterise five Swiss sheep breeds (Blanc des Alpes, Brun-noire du pays, Oxford, Nez noir du Valais and sheep from Hauts-Grisons) (Delacrétaz-Wolff 1997) and differences in frequencies obtained for blood specificities were tested and found to be statistically significant, thus allowing these sheep to be characterised using blood groups.

In sheep, 80 proteins were identified, 14 of which are polymorphic. The serum proteins include transferrin, albumin, haemoglobin, amylase I and carbonic anhydrase II. Of these, transferrin is the most polymorphic serum protein in sheep, with 12 clearly recognised variants (Delacrétaz-Wolff 1997) including transferrin H and K, which were found in 6 sheep breeds from the former Czechoslovakia (Stratil 2009). Nigussie et al (2016). investigated protein (haemoglobin and serum albumin) polymorphism and reported three phenotypes for both loci in indigenous sheep breeds of eastern Ethiopia. The frequency of HbA estimated at 0.77 was higher in Hararghe highland sheep, while HbB was higher in Afar (0.7) and Black head Somali (0.67), with heterozygosity (H_E) ranging from 0.42 ± 0.09 in Hararghe highland sheep to 0.48 ± 0.04 in Afar. The closest genetic relationship was between Afar and Black head Somali (D = 0.01), while Afar and Hararghe highland sheep were more distant apart (D = 0.22). The genetic relationship in the three indigenous Ethiopian breeds was associated with their adaptation to the environment/agroecology. It was demonstrated that the occurrence of errors in sheep pedigrees can be identified by the use of protein polymorphic traits as genetic markers (Wang and Foote 1990). The authors carried out a sheep parentage test using four polymorphic proteins (transferrin, serum arylesterase, haemoglobin and a red-blood-cell lysate protein) and observed that a minimum of 9.2% of the progeny had errors in parentage records. The efficiency of protein genetic markers in solving uncertain parentage cases was 67.2%. An estimate of 58.3% among all cases were solved using genetic incompatibility with transferrin alone.

In cattle, the synthesis of 1000 publications on protein polymorphism by Baker and Manwell (1980) made it possible to establish the phylogenetic tree of 196 breeds. For this study, ten polymorphic loci were identified, including the five previously mentioned blood proteins and five milk proteins. In order to understand the role milk proteins play in determining the quality of milk and cheese, a number of studies have been done using milk from livestock such as cattle and goat milk, though not as many studies have been done in sheep. However, a few significant studies have been done on sheep (Stratil 2009).

Other significant work utilising blood proteins for characterisation conducted on African sheep includes work done on Algerian sheep (Sargent et al. 1999), West African Dwarf sheep breeds (Osamede and Adebowale 2018), on Kenyan breeds and (Sargent et al. 1999) on South African breeds (Sargent et al. 1999).

6.6.3 Genetic Diversity and Population Structure of African Sheep

A new dawn arose for the characterisation of African sheep populations with the discovery of

Fig. 6.37 Noire de Thibar in Zaghouène in Tunisia. (From Djaout et al. 2017, licensed under CC-BY 4.0)

Fig. 6.38 Sicilo Sarde. (From Aloulou et al. 2018, licensed under CC-BY 4.0)

gel electrophoresis, which allowed for protein and later genetic polymorphisms to be separated. The first application of gel electrophoresis was performed by Poulik and Smithies (1958) and quickly spread in the early 1960s, giving rise to a profusion of studies, especially on blood proteins, including the erythrocyte enzyme characterisation work published in 1975 by McDermid and others (McDermid et al. 2009). These foundational studies made it possible to extend the list of markers, including blood polymorphisms, to approximately 30–40 markers per species. The number, however, was still too small to allow for chromosome mapping of breeds. This ultimately led to the development of techniques that were more sensitive, such as those detecting polymorphisms at the DNA level. Among the first such techniques to be developed was the Restriction Fragment Length Polymorphism (RFLP), which was quickly followed by mitochondrial DNA, microsatellites and ultimately genomic sequencing.

Restriction Fragment Length Polymorphisms have been used to characterise African sheep breeds. Investigations on three mutations (Saleh Ahmed et al. 2020) in three candidate genes found in six Egyptian breeds showed that all the breeds did not carry the Fec-B mutation, while the mutations of FecXG and Fec-GH were detected in Rahmani and Rahmani X Barki crosses that are associated with high twinning rates found in the crosses. The characterisation of four Nigerian sheep breeds (Abubakar et al. 2020) using RFLP, namely, Balami, Yankasa, Ouda and WAD, revealed high genetic polymorphisms in the loci studied, high gene flow between the populations, high within-population genetic variances, and suggested that these populations need greater attention to prevent further genetic erosion.

Mitochondrial DNA (MtDNA) sequencing has been extensively used to study domestication of sheep, centres of origin, migration routes followed by the sheep and including studies on how the populations have changed over time. Several studies using MtDNA on African sheep include that by Ghernouti et al (2017). to determine the origin of three Algerian sheep breeds (Ouled Djellal, Rembi and Berbère). The study showed that 87% of the Algerian breeds belong to the haplotype B, with the rest belonging to haplotype C and that the Algerian sheep arrived through three different migration routes, with the Ouled Djellal being the last breed to arrive in Algeria from the Middle East. Similarly, work on Kenyan sheep (Kandoussi et al. 2020) showed that the sheep breeds belonged to haplotype B and had not mixed with sheep from West Africa, while those from Ethiopia belonged to haplotype A and B, with more sheep having haplotype B than A. Phylogeographic analyses of the African sheep breeds identified ancestral haplotypes that are likely to have been introduced to Africa and are now widely distributed throughout the conti-

nent (Poulik and Smithies 1958). The genetic relationship between Moroccan and Iberian sheep using mtDNA sequencing was determined (Kandoussi et al. 2020). This study showed that the first founder Moroccan sheep populations were Iberian in origin (79%), with 21% originating from a territory between the Middle East and the African continent, with population expansion dates estimated at between 7100 and 8600 years BP, respectively. This suggests that neolithisation was introduced through a double influence, from Iberia and from another route, maybe Oriental or sub-Saharan.

In order to investigate the origin of Cameroonian WAD sheep (Djallonke), 16 sequences of a 989 bp fragment of the MtDNA D-loop region in West Cameroon were analysed with previously published sequences from African, European, Japanese and Chinese sheep genotypes (Justin et al. 2022). The phylogenetic analyses revealed that the Cameroon sheep belong to haplotype B and all had a common origin with the African, European and Asian breeds. There is a likelihood that African breeds were domesticated through a series of events.

Wanjala et al. (2021) recently conducted a meta-analysis on 399 previously sequenced African indigenous sheep breeds and showed that overall African sheep populations have undergone selective signatures for adaptation. The results indicated heavy selective pressure, mainly driven by adverse production environments being experienced by East African sheep populations. Analyses of the West and North African sheep populations showed that these populations recently expanded from small populations to the present-day populations (Wanjala et al. 2021) with genetic diversity in different populations mainly being attributed to the effects of breed and location (Aboul-Naga et al. 2023).

DNA microarray studies on African sheep populations have been undertaken on Algerian sheep breeds (Gaouar et al. 2016), with an indication that the populations have been influenced by African and European (especially Italian) breeds. Some of the breeds, especially the Berber and Rembi, and to a lesser extent the Barbarine, have undergone extreme dilution of their genetic diversity due to uncontrolled mating with the Ouled-Djellal breed. The information obtained from this study should be used to inform conservation and population management strategies.

DNA sequencing is an optimal method for the determination of species identity and gene discovery. Until recently, obtaining high-quality genomic sequences for all species was laborious and time consuming (Satam et al. 2023). Several African sheep breeds have been characterised using genomic techniques to determine genetic diversity and breed status (Djaout et al. 2017; Ouhrouch et al. 2021). Genome-wide analysis as well as single nucleotide polymorphism (SNP) genotyping of African sheep breeds have provided information that could guide breeding, conservation and management strategies for the indigenous African sheep populations (Gaouar et al. 2017; Edea et al. 2019; Álvarez et al. 2020; Belabdi et al. 2019; Abied et al. 2021).

Whole genome sequencing has also revealed associations with genes of interest, including genes involved with adaptations of sheep to their environments, disease resistance, phenotypic trait selection among many others (Álvarez et al. 2020; Mastrangelo et al. 2019; Yaro et al. 2019; Wiener et al. 2021), providing key information that can be applied to management, breeding and sheep development programmes. A recent study (Aboul-Naga et al. 2023) identified candidate genes and variants associated with heat stress adaptation in three Egyptian sheep breeds (Saidi, Wahati and Barki). The SNPs associated with heat tolerance were located in MYO5A, PRKG1, GSTCD and RTN1 genes. Association between genetic and phenotypic variations also showed that OAR1_18300122.1, located in ST3GAL3, had the greatest positive effect on heat tolerance. Genome-wide association analysis further identified SNPs associated with heat tolerance in the PLCB1, STEAP3, KSR2, UNC13C, PEBP4 and GPAT2 genes.

6.7 Conservation of Sheep Genetic Resources

Following domestication and the dispersal of sheep throughout Africa, the livestock keepers of Africa have, over the millennia, selected and bred animals to meet their particular needs (Gifford-Gonzalez and Hanotte 2011). This has resulted in a large number of indigenous sheep breeds that have developed a large and diverse range of genes enabling the species to inhabit and produce in a wide range of environments, including environments that are prone to disease, drought and are considered extreme in nature.

Some of the African unique genetic resources are, however, at risk of becoming extinct (Table 6.4) or being subjected to dilution due to indiscriminate cross-breeding among local breeds and between exotics and local breeds. This has led to the continuous genetic erosion and loss of genetic diversity, leading to the loss of breeds carrying unique adaptive traits before these resources have been fully documented and characterised.

The indigenous genetic resources of Africa can make the continent self-sufficient in the production of meat and meat products; hence, there is a great urgency to ensure that they are conserved. Conservation of this unique genetic resource is also important for the African livestock keepers who own and manage these genetic resources and depend on them for their livelihood (Mwai et al. 2015). This would only be possible with concerted efforts.

Two basic strategies for the conservation of indigenous genetic resources can be adopted, in situ and ex situ conservation. In situ conservation involves the conservation of biological elements, including species in the environment where they are naturally found (their natural ecological and livestock production environments or in the wild) (see Sect. 25.3 of Chap. 25 for in situ conservation methods), while ex situ conservation refers to the conservation of biological elements, including species outside the environment where they are naturally found (Maxted 2013). See Sect. 25.4 of Chap. 25 for a detailed discussion on ex situ conservation methods.

Table 6.4 Threatened conventional sheep breeds in Africa that need conservation (AU-IBAR 2019)

Sheep breed	Country
Mouton Kirdi à poils ras	Cameroon
Hamari	Ethiopia
Djallonké	Nigeria, Gambia and Liberia
Red Maasai Sheep	Kenya and Tanzania
East African long-tailed	Kenya and Tanzania
Mouton à laine du Macina	Mali
Mouton Maure à poil long	Mauritania
Mouton Maure poil ras (Ladem)	Mauritania
Landim	Mozambique
Hamari	Sudan
Blackhead Persian	Tanzania
Urambo	Tanzania

The Global Plan of Action (GPA) for Animal Genetic Resources, and specifically The Strategic Priority 10, recognises the need to establish national conservation policies and establish and strengthen in situ and ex situ national conservation programmes, including those found in Africa.

6.7.1 Sustainable Use of Sheep Genetic Resources

More than 6379 documented breeds/populations comprising approximately 30 livestock species have been developed over the 12,000 years since they were first domesticated (Scherf 2000; Gibson et al. 2012). These breeds have developed adaptations that allow them to be productive in a wide range of situations, including some of the most hostile natural environments ever inhabited by humans. These naturally evolving genetic characteristics provide a consistent set of enduring solutions for disease resistance, survival and yield. It is estimated that 35% of mammalian breeds and 63% of avian breeds are threatened with extinction and one breed is lost every week. Although not clearly established, threats to animal genetic resources in developing countries appear to be increasing rapidly, mainly due to rapid changes in production systems and the

extensive use of interbreeding. Emerging threats, such as the implementation of slaughter policies to prevent the spread of diseases in highly traded livestock such as foot-and-mouth disease, and zoonoses such as bovine spongiform encephalopathy and avian influenza, may exacerbate the disease risk of extinction of races in developed countries and also in developing countries. The effective conservation of livestock genetic resources, whether in situ or ex situ, involves the mobilisation of significant social and economic resources over long periods of time. These resources are often available in developed countries, where there is often a high proportion of rare breeds of livestock that are already efficiently preserved. However, the majority of genetic diversity in livestock is found in developing countries, where resources for conservation are scarce. Therefore, it seems likely that difficult choices will have to be made about what to conserve with the limited resources available. Information on genetic diversity is useful in optimising conservation and strategies for the use of agricultural genetic resources. Ideally, it is important to ensure that all existing genetic variations remain available for future use in the most cost-effective manner. In practice, there will often be insufficient resources to maintain the full genetic diversity of a given species. Even when resources are sufficient, we do not have complete knowledge of all the genetic functional variations of a species. Thus, ensuring the conservation of almost 100% of the functional variations would imply the creation of an inefficient process of retaining many more individuals or populations (breeds, memberships) than would be necessary if we had complete information (Gibson et al. 2012).

Since African indigenous sheep breeds play an important role in the livelihood of communal farmers, their utilisation should be approached taking into consideration the socio-ecological system within which they are found. Many factors hinder the sustainable utilisation of sheep genetic resources in rural communities and need to be addressed. These include lack of structured breeding programmes, poor record keeping, poor feed resources, disease and health challenges, as well as lack of technical skills and knowledge (Molotsi et al. 2020). Genomic breeding (see Chap. 20) can be applied to improve areas of environmental sustainability of African smallholder sheep farming systems but must target specific production environments, challenges, as well as the opportunities of smallholder production (Molotsi et al. 2020).

In general, an animal resource management programme is more important and successful when it integrates the triangular holder 'Return with Goal Accomplished' (RGA)-decision makers-researchers (this type of model is very well applied in Morocco, in particular via the national association of sheep and goats, ANOC). However, our experience in Africa leads us to adopt most often a method with two actors, holder RGA-researchers, but this action must go through an important effort of sensitisation of the breeders on the risks of the extinction of the races and the efficiency of African researchers (this type of model is in the process of being applied, in particular in Algeria via the genetics training team at the University of Tlemcen) (Gaouar 2002; Gaouar and de La Biodiversité 2009). The lack of a state animal identification policy in most African countries is a major problem in the management and development of domestic animals.

6.8 Sheep Breeding Goals and Strategies for Sustainable Genetic Improvement

The aim of any breed improvement project is to improve animal traits with a futuristic goal of ending up with an improved population with the best animal phenotype. For sheep, the goals mainly include increased production of meat, milk, wool and resistance to parasites for increased revenue to the farmer (see Chaps. 15 and 17 for a detailed discussion on breeding goals and strategies).

In Africa, the majority of sheep breeds are reared under traditional breeding systems characterised by a lack of improved modern breeding technologies (de Aguiar et al. 2020). There is a need to consider differences in objectives of pro-

duction, farmers' trait preferences as well as breeding practices in various systems of production before designing sustainable breeding strategies to improve productivity (Nigussie et al. 2013) (see Sect. 17.2.1 of Chap. 17). Preferences for traits and order of importance vary depending on the environmental conditions of the region and farming systems (Table 6.5). Breeding objectives that incorporate adaptive traits, reproduction and production could be derived by combining highly favoured and measurable characteristics that are heritable (Molotsi et al. 2020). From an extensive review on relevant genetic traits to sustain smallholder sheep farming systems in South Africa, the authors emphasised growth, carcass and reproduction traits for high input as well as high output farming systems within high rainfall areas; survival, disease or pathogen resistance, adaptability and reproduction could be more important in low input and low output farming systems in drier arid regions, corroborating findings (de Aguiar et al. 2020) on community-based breeding programmes in Brazil. Therefore, selection criteria at the smallholder level should include estimated breeding values of traits that are relevant to the breeding objective as well as preferences of farmers (Amare et al. 2018; Abebe et al. 2020).

Preferred traits in defining breeding objectives under crop-livestock mixed systems were increasing meat production (improving growth rate and conformation), while improving milk yield and meat production were favoured in pastoral and agropastoral systems (Nigussie et al. 2013). General appearance, fast growth and colour were the most preferred characteristics in selecting rams for breeding. For ewes, general appearance and traits related to mothering ability were favoured. Tail type and adaptation to heat stress and feed shortage were preferred in the pastoral production systems compared to agropastoral and mixed crop-livestock systems.

Table 6.5 Trait preference, selection criteria and breeding strategies for genetic improvement of economically important traits in sheep

Preferences by farmers in order of importance	Breeding objectives	Selection criteria	Breeding practices/ strategies	Sheep breed/country
Traits: good mothering ability, coat colour, large body size, short lambing interval, rapid growth rate *Purpose of sheep farming*: Income generation, meat and manure	Production, reproduction and adaptive sheep traits	Body size, brown coat colour, growth rate, horn, ear size and tail type	Selection of rams and ewes within the sheep flock using diverse criteria (body size, coat colour, etc.); culling of sheep due to small body size, unfavourable coat colour, old age, fertility problems for both male and female sheep and poor mothering ability of ewes. Although pedigree-based records are lacking, random mating with communal rams is considered to reduce the effect of inbreeding (Abebe et al. 2020)	Northwest highlands of Ethiopia (Gifford-Gonzalez and Hanotte 2011)

(continued)

Table 6.5 (continued)

Preferences by farmers in order of importance	Breeding objectives	Selection criteria	Breeding practices/ strategies	Sheep breed/country
Growth rate, body size, marketing value	Twin birth type, fast age at first lambing, short lambing interval and fast weaning rate for ewes and rams	Growth rate, body size, weaning rate, body conformation, age at first lambing, lambing rate, drought resistance, colour type, disease resistance, hair type, marketing value, twine rate, horn type, tail type and temperament traits	Village community-based control sheep cross-breeding with communal selected ram use; Private-controlled, mixed-type, village communities-based controlled breeding and random mating practices All breeding strategies and strata had their own source of ram breed type, which could be obtained from their own flock, donor project, purchased from local markets and government supply from the nucleus farm (Amare et al. 2018)	Wollo and Washera highland sheep, Ethiopia (Snowder and Fogarty 2008)
Income generation, breeding, meat production, manure	–	Appearance/body size, colour, fast growth and pedigree	Natural mating, uncontrolled mating due to communal grazing and watering point and lack of a sufficient number of rams (Haile et al. 2015)	North Shoa, Ethiopia (Olivier et al. 2001)
No studies have been done in South Africa to identify traits' preference by smallholder sheep farmers	–	1. Reproduction: wet-dry, fertility (ewes lambing per ewe joined), number of lambs born/ewe joined, number of lambs weaned/ewe joined, Lamb survival; 2. disease and pathogen resistance: faecal egg count, tick resistance; 3. growth traits: birth weight, adult weight; 4. feed conversion ratio; 5. Carcass weight	Application of traditional breeding and genomics will enhance sustainable genetic improvement in low-input farming systems and commercial intensive sheep farming (Molotsi et al. 2020)	South Africa (McKinnon and Rocha 1985)

(continued)

Table 6.5 (continued)

Preferences by farmers in order of importance	Breeding objectives	Selection criteria	Breeding practices/ strategies	Sheep breed/country
Cultural/family traditions, food source for family, savings, personal fulfilment and income generation	Adaptation of the animals to the climate and management conditions of the region, the resistance to diseases and productive performance	Adaptability, disease resistance, host resistance of worms, growth rate, fertility, longevity, body conformation, body size and age at first lambing	Community-based breeding programmes which take into account the desires and needs of the local farmers (de Aguiar et al. 2020)	Brazil (Maxted 2013)

The most economically important trait in sheep is reproduction, which is considered to be complex due to the fact that its expression is closely tied to other traits (Molotsi et al. 2020; Snowder 2008). Reproduction is measured by component traits, including the number of lambs born per ewe's lifetime, or number of lambs weaned per ewe lifetime, litter size, conception rate, lamb survival and mothering ability (Snowder and Fogarty 2008). Reproductive performance has been defined as the total weight of lambs weaned per ewe joined (Olivier et al. 2001), which could be improved genetically by direct or indirect selection. As a composite trait, genetic improvement can occur by selecting individual component traits, some combinations of individual component traits, or direct selection for the composite trait. It has been considered that rather than selecting for a single component trait, selection for a composite trait, for example, litter weight weaned, will improve reproductive efficiency under most production and environmental systems (Snowder 2008). Furthermore, selection for litter weight could lead to a balanced biological composite trait with favourable responses in component traits like fertility, number of lambs at birth, lamb survival, lactation and lamb growth. Despite the fact that reproduction and survival traits are generally lowly heritable in livestock, genetic progress was possible for over 20 years of selection in South African sheep.

Strategies for genetic improvement could follow three pathways (Tibbo et al. 2006). They include (i) selection within breed, (ii) selection between breeds and (iii) cross-breeding (see Sect. 17.3 of Chap. 17). Due to the low productivity of indigenous African sheep breeds, strategies involving cross-breeding in different regions to upgrade performance have generally been unsuccessful due to poor adaptability of crossbreds with high exotic blood (Gizaw et al. 2013). The exception is Dorper sheep of South Africa, which is the most successful sheep breed in Africa developed through cross-breeding (Sect. 17.3.1 of Chap. 17). Indiscriminate cross-breeding has proven to be unsuitable in many production areas (Gibson 2007). Current strategies for breeding of sheep involve indiscriminate mating and cross-breeding, village-controlled breeding and privately owned controlled breeding (Amare et al. 2018). Smallholder sheep producers achieve their breeding objectives by introducing new superior rams from highly performing indigenous breeds for cross-breeding with local breeds.

6.8.1 Pure Breeding

Selection and mating within a breed based on measurable productivity traits such as growth, survival and litter size (Tibbo et al. 2006) constitutes pure breeding. Considerable genetic improvement is possible when within-breed genetic variation for traits of interest is substantial. To achieve a successful within-breed improvement programme, there is a need to define overall breeding objectives, characterise production systems, identify suitable breeds, identify the breeding goal traits and derive goal values for each of the traits. Breeding goal traits should have (i) large genetic variability; (ii) easily and cheaply measurable, or must have high

genetic correlation with a trait (indicator trait) that is easily measurable, has high heritability or can be measured earlier in life than the goal trait it represents; and (iii) desirable economic value, either as a marketable commodity or as a means of reducing production costs (Tibbo et al. 2006).

To guarantee long-term genetic improvement, indigenous genetic diversity conservation, protection of ecosystem health, as well as improvement of livelihood, a participatory programme has been proposed (Tibbo et al. 2006). The authors proposed an open-nucleus breeding system with flocks on government ranches at topmost of a three-tier system of flocks. High-performing breeding ewes are brought in from sub-nucleus herds for pure-breeding to nucleus flocks in the ranches. Superior rams from the ranches are selected and distributed to participating farmers in sub-nucleus flocks for mating. Afterwards, village flocks receive selected superior rams from the sub-nucleus herds. To ensure success, the programme should be managed by a nationally authorised Animal Genetic Resources Institution, collaborating with research institutions and overseeing all activities related to the programme.

As a case study in Kenya demonstrated (Zonabend König et al. 2017) pure breeding of Red Maasai under adverse environmental conditions improved meat production and livelihoods. With a well-designed nucleus breeding scheme, considerable genetic gain in live weight and carcass weight at the commercial level was realised, although there was a lag period until the improvement in any trait reached the commercial tier. However, the selection of female replacements in the commercial tier would reduce the lag but requires resources for extended sheep recording. The predictable gain in a low heritability trait, such as survival, is low. Cross-breeding of Red Maasai with Dorper was not recommended for harsh environmental conditions, except that Dorper is used as a terminal sire breed for crossing with Red Maasai ewes in less harsh environments. See Sect. 17.4 of Chap. 17 for examples of other indigenous sheep breeds (Djallonke and D'man) improved through targeted selection.

It has also been demonstrated in the dairy industry within the European setting that the most effective selection scheme for local dairy sheep breeds is based on pyramidal management of the population with breeders of nucleus flocks at the top, where pedigree and official milk recording, artificial insemination, controlled natural mating and breeding value estimation are carried out to generate genetic progress (Gibson et al. 2012). Genetic improvement realised is transferred to commercial flocks through artificial insemination or the use of superior rams for natural mating.

6.8.2 Community-Based Breeding Programme

Livestock improvement programmes in Africa have not always achieved high levels of success in smallholder settings, especially those in low-input production systems and with small flocks of sheep and goats. In these setups, farmers have limited access to breeding stock and rely mainly on traditional community breeding practices. The community-based breeding programme (CBBP) was developed as a more suitable alternative for such smallholder settings and has seen greater success in some African countries, especially in Ethiopia, where it has been widely implemented (Gizaw et al. 2013; Haile et al. 2019; Weldemariam and Mezgebe 2021). The CBBP's success comes from the involvement of farmers in the design of breeding programmes from the project inception stage, through to implementation. In this model, decisions are made by the farmers and they actively take part in the breeding improvement programmes, and their views, choices, and decisions are taken into consideration and incorporated. The farmers are organised into groups and receive technical input and support from extension workers and government- and institutional-based breeders who transmit sound breeding methods. The males used for breeding are selected from the community, and thus, local and indigenous genetic resources have a great influence on the breeding outcomes. This approach has seen small but significant improvements in the productivity of indigenous breeds, without undermining the breeds' resilience, genetic diversity and with interventions that are within the

reach of the community and are thus affordable and inexpensive (Weldemariam and Mezgebe 2021).

6.9 Responses of Existing Sheep Breeds to Selection

Phenotypic changes under selection of sheep are ongoing, resulting in a variety of current breeds adapted to various environments for the production of meat, milk and fine wool. In a broader sense, genome-wide analysis of the world's sheep breeds revealed strong selection signals with 31 regions comprising genes for coat pigmentation, skeletal morphology, body size, growth and reproduction, and adaptation to diverse environments (Kijas et al. 2012; Fariello et al. 2014). The strongest selection signal occurred in response to breeding for polledness (Kijas et al. 2012). Some indigenous sheep breeds of Africa (Djallonke and D'man) have been improved for some economic traits through targeted selection (see Sect. 17.4 of Chap. 17).

Limited number of studies have been reported on the evaluation of direct and correlated selection responses for economically important traits in African sheep breeds. A study involving Merino sheep of South Africa showed that direct selection for total weaning weight (Table 6.6) would be the best selection criterion to improve reproductive performance without increasing litter size at birth (Olivier et al. 2001). This is important if an increase in the number of lambs is not desirable, where lambing and weaning percentages are high.

6.9.1 Responses to Selection for Meat, Milk and Wool Traits

6.9.1.1 Responses to Selection for Meat Traits

Litter weight weaned is an important trait to target when the aim is to increase the overall reproductive rate in sheep because it has a positive and direct impact on the income of a farming enterprise (Yaro et al. 2019; Olivier et al. 2001). It can be used as a biological index for selection (Yaro et al. 2019). Although the heritability estimates are low (0.1–0.19) for litter weight at birth (Bemji et al. 1996; Boujenane et al. 2013) and at weaning (Boujenane et al. 2013; Olivier et al. 2001), intense selection can result in a favourable selection response given their large phenotypic variances (Snowder 2008). Long-term selection for litter weight weaned would result in a balanced biological system within the environment and production system selected. Although a small negative genetic correlation may exist between litter weight weaned and grease fleece weight, there is no other antagonistic genetic correlation with litter weight weaned.

Selection responses for weaning weight and total weaning weight (TWW) were expressed as the average gain (kg) per generation, and for the number of lambs born and the number of lambs weaned as the average gain in the number of lambs born or weaned per generation (Olivier et al. 2001). Expected direct selection responses by two populations of Merino sheep were higher for TWW compared to the other reproductive traits studied (Table 6.6). Furthermore, correlated selection responses per generation based on TWW were lower for all traits compared to expected direct selection responses.

Reports indicate that the Dormer direct breeding value for weaning weight increased by 0.12% during a period of 17 years, while post-weaning weights improved by 0.32% per annum, and the average predicted direct breeding values of birth weight decreased by 0.055% (Zishiri 2009). The Ile de France sheep breed saw an increase in predicted breeding value at birth (0.025% per annum), averaged direct breeding values for pre-weaning weight and weaning weight increased at an annual rate of 0.23% and 1.21%, respectively. In the Merino Land sheep, the predicted direct breeding value for birth weights decreased by 0.04% per annum, and pre-weaning and weaning weights increased by 0.36% and 0.10%, respectively. For D'man sheep, estimated annual genetic progress was very small, being 0.0009 lambs for litter size at birth and − 0.0078 kg for ewe's body weight (Boujenane et al. 2013).

Table 6.6 Heritabilities, expected direct and correlated responses to selection for some reproductive traits in sheep

Sheep Breed	Country	Trait	Heritability	Direct selection response per generation	Correlated response with total weaning weight	References

[a]Actual estimates

6.9.1.2 Responses to Selection for Milk Production

Milk production is part of the objective of sheep production in pastoral and agropastoral systems, but not common in the mixed crop-livestock farming (Nigussie et al. 2013). The expected gain in low heritability traits like milk yield and survival is low (Zonabend König et al. 2017). The low heritability for milk yield in African sheep populations is likely due to the fact that sustained direct selection for milk yield has not been implemented for most African breeds. Within the European setting, realised genetic gains of most breeds show an increasing trend of milk production as a result of the development of management techniques (Carta et al. 2009). However, in semi-extensive systems where grazing represents an important portion of feeding, this trend is lower and irregular because of annual variations of herbage availability to which these systems are very sensitive (Carta et al. 2009).

6.9.1.3 Responses to Selection for Wool Traits

Genetic trends observed in Karakul sheep (Greeff et al. 1993) indicated that selection for pelt traits can be relatively effective based on realised heritabilities of 0.20, 0.34, 0.63 and 0.56 for pattern, hair quality, hair length and curl development, respectively. Corresponding estimates for mean

annual response to selection were 2.52%, 1.31%, 2.96% and 7.1%. The control flock did not remain genetically stable, as pattern and hair quality had small positive changes, whereas curl development and hair length had small negative changes. According to the authors, responses to selection compared favourably with characteristics in other sheep breeds. Annual responses of between 1 and 3% were obtained for hair quality, hair length and pattern. A response of more than 7% per year was reported for selection for a decrease in curl development. The relatively high responses indicated that pelt traits can be precisely estimated.

6.9.2 Main Environmental Selection Factors and Limitations in Responses

Estimates of heritabilities for animal genetic and permanent environmental and maternal genetic effects are small as a result of substantial effects of environmental factors (season of breeding, year, age of ewe, breed of ewe and hormone treatment) on reproductive traits and to non-normal distributions of traits (Rosati et al. 2002). As further reviewed by the authors, low heritability of reproductive traits is likely due to a larger proportional influence of environmental factors, little genetic variability for fertility, litter size, lamb survival and lambing frequency and other reproductive traits.

Designing efficient selection and breeding strategies for genetic improvement and appropriate genetic evaluation of local breeds involves precise estimates of genetic parameters (Boujenane et al. 2013; Safari et al. 2005), which include heritabilities, repeatabilities, genetic and phenotypic correlations. Lack of records on the animals or lack of continuity in data submission constitutes the most serious challenge to genetic parameters' estimation and genetic progress (Zishiri 2009). Estimates are often biased due to a few records or inconsistencies in data structure.

6.10 Sheep Production Capacity of Africa in Terms of Milk, Meat, Wool and Skin

6.10.1 Sheep Milk Production

Sheep milk production (Fig. 6.39) and consumption are important to many African nations. Sheep milk provides a wide spectrum of nutrients, including proteins and vitamins and has been found to be richer in fat content, solids and minerals when compared to cow milk, making it ideal for cheese production. Sheep milk provides

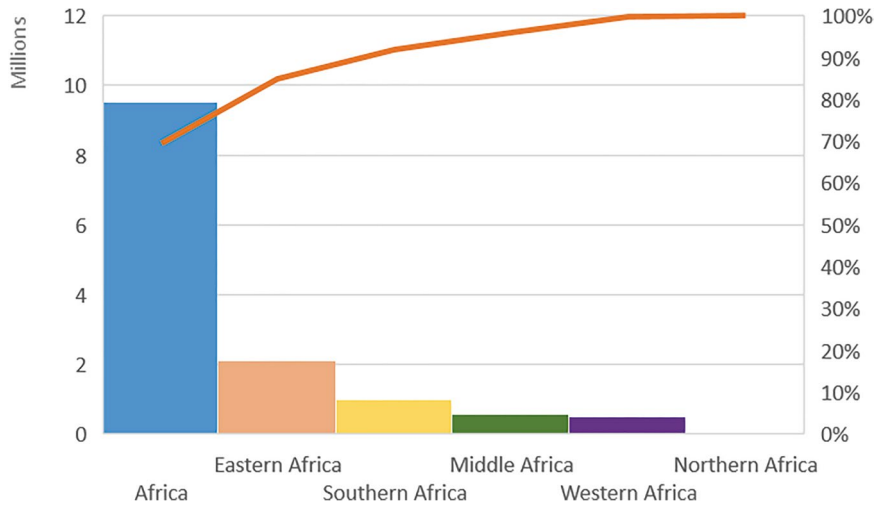

Fig. 6.39 Sheep milk production in Africa (in millions of tonnes), 2009–2019 (FAOSTATS 2021)

an important resource to households in terms of nutrition, especially in arid and semi-arid regions. It is also used to make a variety of products, including cheese, yoghurt and butter, which provide additional sources of income for households. There are relatively few sheep breeds that have been developed for dairy, and the most productive breeds are the Lacaune, East Friesian, Sarda, Assaf, Chios and the Awassi breeds (Skapetas and Kalaitzidou 2017).

6.10.2 Meat Production

Africa produced approximately 1.6 million tonnes of sheep meat (Fig. 6.32), generating approximately USD 8.3 million in 2019 (FAOSTATS 2019). Indigenous sheep produced approximately 1.4 million tonnes in 2019. Sheep production in Africa has seen a steady increase from 614,915 tonnes produced in 1970 (FAOSTATS 2019). North African countries are the largest sheep meat producers in Africa (Fig. 6.40). Specifically, Algeria is the largest sheep meat producer in Africa (331,967 tonnes in 2019), followed by Sudan (265,000 tonnes in 2019) and Morocco (178,770 tonnes in 2019) (FAOSTATS 2021).

6.10.3 Wool Production

Wool production was of major importance throughout human history (Ryder 2007) and was the first product to be involved in the international trade of goods. In addition to being used to make clothes, wool is used to make carpets, blankets, house rugs, felt and many other products. While African wool production only represents 3% of world fibre production, sheep fibre and wool are very important to the economies of many African nations. Africa produces a total of 203,000 tonnes of greasy wool, with the North African countries being the largest producers (Fig. 6.41) (FAOSTATS 2019, 2021). Morocco is the largest greasy wool producer at 64,000 tonnes in 2019, followed by South Africa, Algeria and Ethiopia (42,000, 34,700 28,500 and tonnes in 2019, respectively) (FAOSTATS 2019).

Greasy wool production (Fig. 6.41) provides farmers with alternative sources of income, a trade and a way of life for many communities. The gradual increased use of synthetic fibres has resulted in a decrease in the demand for wool, which has caused a drastic impact on sheep breeds kept primarily for wool production. Sheep in Africa are primarily kept for meat, fat, milk and skin, and as a result of this, production of wool

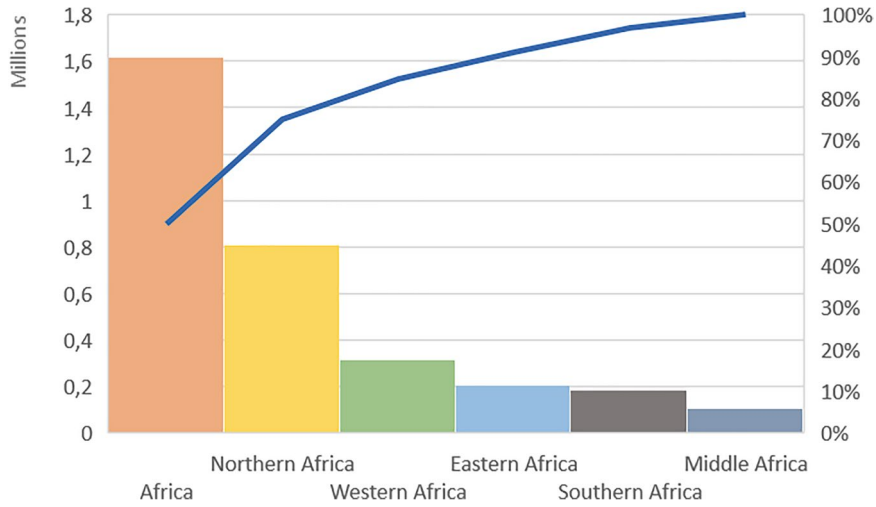

Fig. 6.40 Sheep meat production in Africa (in millions of tonnes), 2009–2019 (FAOSTATS 2021)

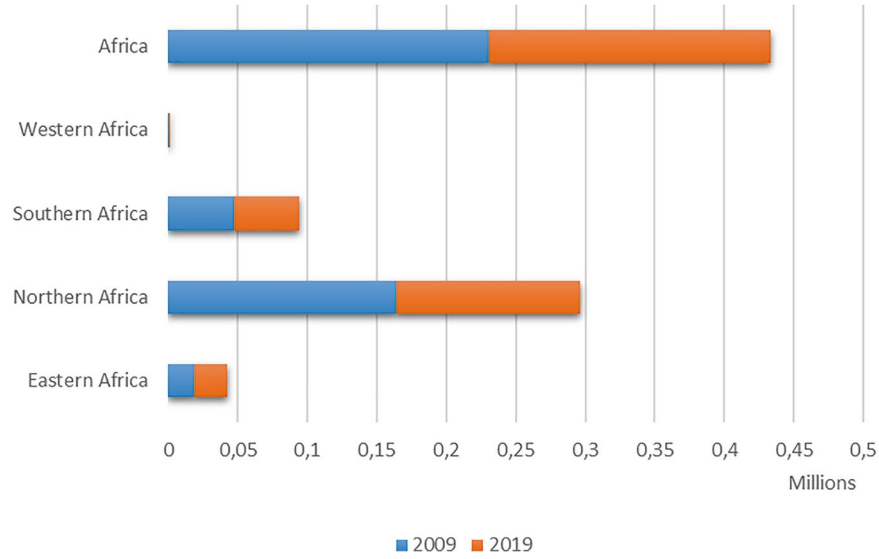

Fig. 6.41 Sheep greasy wool production in Africa (in millions of tonnes), 2009–2019 (FAOSTATS 2021)

from sheep has been undermined, with many African nations not maximising wool farming. Wool farming is also a profitable venture and can increase sheep farmers' income by at least 20%.

6.10.4 Skin Production

Raw skins and hides are by-products of sheep that are reared and slaughtered for meat. The raw skins and hides are direct inputs to the leather industry. Africa produced approximately 282,323 tonnes of raw skins in 2012 (Table 6.7), most of which is exported, thus earning many countries much-needed foreign exchange. Ethiopia, for example, earned USD 139 million in 2010 from exports of finished leather products (Central Statistical Authority 2011).

Sheepskin produces high-quality leather that is used in the production of many leather goods, including shoes, gloves and clothing. The sheep fleece is also used to make a wide range of products, including fibre, string, soft wool lining and coverings (Skapetas and Kalaitzidou 2017).

6.11 Challenges to Sustainable Genetic Improvement in the Sheep Industry

Several technical and non-technical constraints militate against successful genetic improvements and sustainability in the sheep sector (Pollott and Wilson 2009; OECD and FAO 2016; Tibbo et al. 2006; Wiener 1994), which are briefly highlighted below.

- Indifferent attitude of the population to low genetic potentials of african indigenous sheep breeds: Although the low production potential of African indigenous sheep is not a constraint to genetic improvement, an indifferent attitude by the population limits proper planning (poor participation of livestock farmers and other stakeholders) in the design for implementation of more appropriate genetic improvement programmes.
- Limited information on the characterisation and conservation of most African sheep genetic resources.

Table 6.7 Global sheep raw skin production (tonnes) 2000–2012 (FAOSTATS 2021)

	Year		Change (%) 2000–2012		Contribution 2012
s	2000	2012			
Asia	851,791	1,049,474	23.2	11.7	
Africa	200,064	282,323	41.1	3.15	
Oceania	251,136	7,223,508	2776	80.7	
Europe	376,886	299,085	−20.6	3.34	
EU (28)	236,966	206,245	−13	2.30	
Americas	92,311	93,160	0.92	1.04	
World	1,772,189	8,947,550	404.89	100	

- Uncontrolled cross-breeding is the foremost cause of genetic erosion of sheep breeds in Africa (Leroy et al. 2016).
- Lack of skilled manpower: The design and implementation of a sound breeding improvement programme requires trained experts, which are often lacking.
- Highly mobile small flock sizes, single-sire flocks, lack of animal identification, lack of performance and pedigree recording due to the low level of literacy of farmers.
- Inadequate feed supplies and poor animal nutrition.
- Widespread distribution of livestock diseases.
- Poor Infrastructural Facilities (transportation, marketing and implementation of artificial insemination): Many countries in sub-Saharan Africa are characterised by poor road network systems, which make transportation of animals and semen from one location to another difficult. It is also difficult to successfully implement artificial insemination, which involves the production, collection, storage, distribution and effective use of semen. The marketing of agricultural products is also limited by poor infrastructure.
- Non-technical constraints include the absence of government-driven clear livestock development policies and strategies, as well as incentives or credit facilities for farmers.

6.12 Conclusion and Future Prospects

The sheep industry remains one of Africa's most promising small ruminant sectors, with huge genetic resources of over 363 breeds. A limited number of these breeds have been characterised using phenotypic (qualitative and quantitative) traits, as well as molecular markers, which demonstrated evidence of high within-breed genetic diversity. Growth in demand for meat from sheep is almost entirely met by supply from indigenous production, with limited import compared to other livestock species. Despite substantial challenges to genetic improvement, the sector has huge potential to improve food security and encourage economic development in most countries in sub-Saharan Africa. To drive sustainable breeding and genetic improvement programmes, there is an urgent need to intensify efforts on characterising more African sheep breeds, conserving the existing diversity, developing human resources, encouraging cooperative farming among farmers, and forming breed societies. Given the enabling environment along with a simple and well-designed nucleus breeding programme, possibilities exist for improving the sheep genetic potential for more efficient production of meat, milk, wool and skins using traditional breeding (see Chap. 17) and recent genomic

techniques, as well as relevant modern technologies as outlined in Chap. 21. This will also involve re-orientation of the role of governments and other relevant institutions to take appropriate responsibilities.

Acknowledgements The authors would sincerely like to acknowledge in a very special way the African sheep keepers, managers, breeders and processors who, through their utilisation of the sheep in Africa, have enhanced their conservation. They are also sincerely thankful to individuals who provided photographs of various African sheep breeds included in this chapter. Citations were provided for photographs obtained from the literature, and sources of information were acknowledged using references.

7 African Domestic Poultry Genetic Resources, Diversity, and Unique Features

Tadelle Dessie, Christian K. Tiambo, Liveness J. Banda, Raman A. Lawal, Sheila C. Ommeh, Timothy Gondwe, Esatu Wondmeneh, Matthew A. Adeleke, and Olivier Hanotte

Abstract

This chapter provides a detailed account of African domestic poultry genetic resources, their diversity, and unique features. It aims to bring together information to provide a comprehensive picture of the topic. Section 7.1 introduces African poultry genetic resources, their importance, and previous interventions conducted to better utilize this important resource. Section 7.2 deals with the origin of poultry genetic resources and their dispersal into Africa. The introduction of domesticated chickens into Africa is not well documented. Although indigenous birds have several adaptive traits and associated genes that are important in the tropics, the real value of indigenous chicken breeds is often underestimated. They have a poor appearance, relatively low productivity, and are consequently considered to have low value compared to their improved commercial counterparts. Chicken genetic resources are endangered and underconserved. However, there has been recent emphasis on local chicken breed development and conservation, which has gained attention. The section demonstrates how chickens have become a key part of the African poultry production system and how they can remain vital and instrumental, considering the current climate change. Sections 7.3, 7.4, 7.5 and 7.6 describe the available chicken and duck resources in different parts of Africa and out-

line their unique features and population estimates. Considering the population size of these genetic resources, conservation efforts to support their utilization are addressed in Sect. 7.8. Furthermore, the importance of conserving poultry genetic resources using germplasm cryobanking (cryoconservation) is described. Section 7.10 describes genetic improvement attempts in Africa involving indigenous chicken populations. The information appears to be limited to a few examples, as not many improvement programs are ongoing, and information on some programs is not available. Section 7.11 describes the major constraints of poultry production in Africa, followed by the economic contributions in Sect. 7.12. The last chapter implies the way forward in the utilization of poultry genetic resources in Africa.

7.1 Introduction

7.1.1 Overview of African Poultry Genetic Resources

Poultry genetic resources have existed for thousands of years and many generations. They are found in a diversity of environments and production systems, and they were subjected to breeding improvement and natural selection (FAO 2014). The chickens, once domesticated, have adapted to specific environmental and farming conditions, resulting in within-population unique gene combinations. When direct measures of genetic diversity are unavailable, the number of breeds and ecotypes may provide a first indication of the farm species' genetic diversity. Breeds are commonly classified as indigenous or exotic, with indigenous populations often present in low-input–low-output production systems and exotic ones referring to commercial lines and imported fancy breeds. The poultry genetic resources, the entire chicken populations, exotic and commercial, contain genetic material of present or future value. The diversity of poultry genetic resources reflects a long history of natural and human selection as well as crossbreeding among not only domestic chickens but also, as recently discovered, with wild *Gallus* populations outside the center(s) of domestication (Lawal et al. 2020; Wang et al. 2020; Lawal and Olivier 2021).

Beyond their potential use as inputs to improve productivity and other traits of interest, understanding the resources and designing interventions to conserve and utilize species, breeds, and ecotypes is vital to benefit the households that depend on them. The poultry genetic resources are a starting material for breeding activities to improve the traits of interest. Conserving genetic resources is a means of safeguarding the resources

further to be utilized as food and other purposes considered necessary by the users. While in situ in vivo, we may call it conservation through utilization. Here, the utilized genetic resources are a warranty for their conservation. Conservation efforts should ensure broad-based genetic diversity to ensure availability for use by present and future generations. This can only be possible by knowing the within-species diversity and keeping important information in an orderly manner in breed databases such as the (DAGRIS 2021; DAD-IS n.d.).

Domestic chickens first appeared in Africa many centuries ago and are now an established part of the African agricultural landscape (Alders and Pym 2009). There are about 126 poultry genetic resources regarded as varieties or ecotypes in Africa (http://dagris.ilri.cgiar.org/). Most of them are hardly studied to show their actual worth, but some studies have revealed their potential as better-performing and adapted chicken populations. There has still been little effort in African countries to conserve the local chicken breeds or lines (Manyelo et al. 2020). Although African poultry genetic resources are resistant to prevalent disease, they are also known for low productivity (Dessie 2003). Poultry genetic resources in Africa are admired for their tolerance to common poultry diseases and uncertainty in feed quality and availability. They exist with minimal input supply (Desta and Wakeyo 2012). However, any improvement in the productivity of local chickens will require close attention to nutritional, breeding, and health aspects. Smallholders in Africa are the custodians of poultry genetic resources, and they kept them under a traditional scavenging system (Magothe et al. 2012a; Desta et al. 2013). Interventions to introduce high-performing chicken strains into Africa have been largely unsuccessful (Tadelle et al. 2003; Wondmeneh et al. 2016). Poultry keepers in African villages cannot afford the high input requirements (housing/shelter, commercial diets, and strict disease control/vaccination programs) associated with more genetically efficient breeds (Tadelle et al. 2003).

7.1.2 Importance of African Poultry Genetic Resources

Although indigenous birds have several adaptive traits and genes with utility in the tropics (Horst 1989a), the real value of indigenous chicken breeds is often underestimated, primarily due to their poor appearance, relatively low productivity, and alleged low "commercial" values. African poultry genetic resources are neglected, and relatively little attention has been given to them in the research and development agendas. Hodges (1990) stated that developing countries, in most cases, opt for high-performing commercial breeds from developed countries to increase animal productivity through crossbreeding or, if conditions allow, by breed substitution without adequately investigating the production system and potential of the indigenous birds. Although poultry (both meat and eggs) is an essential source of food and a means of investment that is important to the welfare of women and children in traditional and low-input systems, an alarming 34% of all chickens in Africa are at risk of being lost (FAO 2000).

7.1.3 Initiatives to Utilize Indigenous Poultry Genetic Resources

Emphasis on local chicken breed development and conservation has gained attention through several pioneering programs led by national institutions. For example, independent indigenous chicken improvement programs have been established involving promising local chicken breeds in Kenya (KALRO 1 and KALRO 2) (Miyumo et al. 2023), Ethiopia (Horro and Tilili) (Mulugeta et al. 2020), Tanzania (Horasi) Esatu 2022 (a) (Esatu et al. 2022), Nigeria (Noiler and Funaab-alpha) (Bamidele et al. 2019), and Cameroon (IRZ (Van Marle-Köster and Casey 2001)). They aim to improve egg production, growth, survival, and age of the first egg. These chicken strains were identified through previous characterization

and evaluation studies and possessed qualities appreciated by the poultry producers and consumers. Five of these programs were established through the support of the ILRI-led African Chicken Genetic Gains (ACGG) and Tropical Poultry Genetic Solution (TPGS) programs, while the programs in Nigeria and Cameroon were started earlier. Seven of these programs are applying mass selection supported by BLUP (Best Linear Unbiased Prediction) techniques to select the best-performing chickens based on the estimated breeding values. Further, there is the potential in the future of applying genomic selection with the characterization of the breeds at the genome level. This is currently being explored through collaboration between the newly established Center for Tropical Livestock Genetics and Health (CTLGH) and national partners. The CTLGH poultry program also includes the identification of local ecotypes and ex situ PGC (Primordial Germ Cell) conservation initiatives (see Sect. 7.8).

7.2 The Origin and Purpose of African Poultry in Relation to African Farming Systems: A Historical and Production Systems Perspective

7.2.1 Origin of Domestic Chicken and Its Dispersal to Africa

Domestic chickens are assigned to the genus *Gallus,* which includes four extant wild species. Several studies support Asia as the continental origin of chicken (Wang et al. 2020; Fumihito et al. 1994; Peters et al. 2022; Clutton-Brock 1993) with the specific geographic domestication center likely in Southeast Asia (Wang et al. 2020; Fumihito et al. 1994). One of the red junglefowl subspecies, i.e., *Gallus gallus spadiceus,* is the primary ancestor from which the chicken was domesticated about 8000 years ago (Lawal et al. 2020; Fumihito et al. 1994; Peters et al. 2022). However, subsequent genetic introgression after domestication from different *Gallus* species (*G. lafayettii, G. sonneratii*, *G. varius*) and the other four *Gallus* subspecies (*G. g. bankiva, G. g. gallus, G. g. jabouillei*, *G. g. murghi*) have been reported[2,325]. The consequence of these introgression episodes may explain the observed high genetic diversity seen today in modern chickens and, perhaps, also their rapid adaptation to new environments. From Southeast Asia, the domestic chicken migrated, as human livestock commensal, to other parts of the world, adapting to different environmental conditions.

The introduction of domesticated chickens into Africa is not well documented. Clutton-Brock (1993) and Mwacharo et al. (2013) have summarized the archaeological findings on the domestic fowl in Africa. It is worth emphasizing here that Egypt played a key role in chicken introduction to the African continent. First, its connection to the Fertile Crescent presented an important trading network between Africa and South Asia. Second, the early civilization of Egypt attracted international diplomatic relationships with the Persians and with the North of the Mediterranean Sea, especially during the Egyptian Greek and Roman reigns. Egypt was therefore an important route of entry and dispersion of chicken to the continent, either through the Mediterranean coast or overland.

Domestic chicken bones have been found in Ethiopia as early as 1055–825 BC (D'Andrea et al. 2011). In East Africa, they have been found in two Iron Age sites in Mozambique and South Africa from the eighth century. In South Africa (Plug 1996), mentions that they were uncommonly found in early Iron Age sites. In West Africa, they have been excavated from the Iron Age site of Jenne-Jalo in Mali, dating from 500 to 800 AD.

Also, multiple lines of evidence support different timescales and patterns of chicken dispersion to the African continent (Adebambo et al. 2010; Muchadeyi et al. 2008; Mwacharo et al. 2011; Razafindraibe et al. 2008). Two migration waves and entry points have been proposed. (i) An overland entry following possibly the Berbers and the Phoenician expansion along the North of Africa and across the Sahara (Kiple and Ornelas 2000), with most domestic chickens on the North, West, East, and South parts of the continent likely

originating from this wave. This wave might be characterized by a single mitochondrial DNA haplogroup present in all African countries but also commonly found on the Indian subcontinent (Adebambo et al. 2010; Muchadeyi et al. 2008; Mwacharo et al. 2011; Hassaballah et al. 2015). (ii) A more recent arrival of chickens to Africa likely followed the Indian Ocean maritime trading routes along East Africa, the Red Sea, India, and Southeast Asia coastal areas (Fuller and Boivin 2009).

Today, chickens play significant roles in the cultural life of rural people. In Africa, different indigenous chicken types are valued for cultural, social, and religious functions (Sonaiya 1999). Basic features with sociocultural significance are the color, sex, and comb type of the bird, and these are often related to the spirituality of their owners(Sonaiya 1999; Tadelle 1996).

7.2.2 Domestic Chickens as a Key Part of the African Farming Systems

At the onset of domestication, chickens were likely kept for cultural and recreational purposes, including cockfighting. In Africa, the precise time of transition from a cultural to a food-producing animal is unknown, but it may have followed urbanization and/or cultural habit changes as observed in Europe around 1000 AD (Loog et al. 2017). Since then, chickens have remained a key part of the African farmyard, and globally, they have become the most important poultry species (FAO 2014). It is the most common domestic animal on the African continent, and it is now kept primarily for meat and eggs and mostly under the custody of women and children.

There are two major poultry production systems in Africa: commercial (intensive) and indigenous village chickens (extensive). In Africa, the cost of raising commercial chickens is high. As a result, most poor African farmers keep indigenous village chickens within a small-scale farming system. In Tanzania, indigenous chicken represents 94% of the chicken population (R.I.U 2012), a proportion similar across the continent. Like their wild ancestors, indigenous village chickens are natural scavengers. They are raised under an extensive system of production where they forage on free range and under natural environmental conditions. Though the productivity of the extensively raised village chickens is less than the commercial chickens, the overall input is minimal, especially for housing, disease control, management, and supplementary feeding (Alders et al. 2018). Thus, it is economically efficient to be kept by farmers. Indigenous chickens represent an important genetic resource for breed improvement programs in Africa. They are characterized by high genetic diversity, adaptation to common poultry diseases, and poor-quality feed (Bettridge et al. 2018; Lyimo et al. 2014). Hence, they represent a key resource to enhancing food security, nutrition improvement, and economic growth (Alders and Pym 2009; Melesse 2014).

7.2.3 Challenges with Small-Scale Backyard Farming

Small-scale farming systems are faced with multiple risks, including a high mortality rate associated with predator attacks and disease outbreaks. A sudden change in the weather cycle affecting the availability of feed resources due to droughts can also increase mortality (Ayanlade et al. 2017; Debela et al. 2015). As part of their survival instinct, indigenous village chickens mostly roost in trees, high fences, or other elevated structures. However, deforestation, urbanization, and climate-induced fire outbreaks constitute a current threat to them. The lack of an organized marketing system, capital, and, in the event of a disease outbreak, the lack of adequate vaccination programs are key challenges facing backyard farming. All these pose risks to productivity, economic growth, and general rural development.

7.2.4 The Impact of Climate Change on Poultry Farming in Africa

Smallholder farmers significantly contribute to the food supply in Africa (Kamara et al. 2019). Their daily survival is also dependent on the livestock they keep, both for food and income. Though Africa, as well as poultry farming, contributes the least to greenhouse gases, compared to other continents and ruminant livestock species (Abioja and Abiona 2020), the impact of climate change is expected to be severe on the continent, disrupting natural ecosystems (Ngaira 2007), causing famine, starvation, and death. For instance, a warmer climate will lead to drought, creating competition for water, forages, heat stress, and disease outbreaks. Heat stress, for instance, has a direct impact on growth, productivity, and mortality rate of poultry (Liverpool-Tasie et al. 2019; Tankson et al. 2001). Though this may be severe, indigenous village chickens can serve as a key model to mitigate against the impact of climate crises on the continent through adequate breeding improvement programs. Their genomes have adaptively evolved to better cope with extreme climatic variations, as shown, for example, by a recent study including 245 Ethiopian indigenous village chickens from different agro-ecologies (Gheyas et al. 2011).

7.3 The Current State of Knowledge on Poultry Genetic Resources: Introduction and Distribution in Africa

According to (AU-IBAR 2019), a diversity of both local and exotic poultry breeds is found on the continent. Chickens have the largest number of "breeds" (329), followed by ducks (41) and guinea fowls (40); other species, like domestic ostriches and turkeys, are also present but in much lower numbers. Local breeds follow the path of smallholding in rural communities, while exotic breeds are for commercial production, and they are common in peri-urban areas. The increased proportion of exotic breeds observed across the continent reflects the demand for livestock products following the population size increase. Except for dual-purpose breeds that are used in crossbreeding programs, exotic strains are usually raised in confinement following an all-in-all-out system. In this respect, they do not pose a threat to local breeds. According to (DAD-IS n.d.), West and Southern Africa host the largest number of described "breeds," followed by East and Central Africa, with a lower number of breeds reported for North Africa. A high number of plumage and morphological phenotypes may be found within the indigenous chicken population, some of which have been associated with specific breed types (Table 7.1). Also, there are genes in indigenous chicken populations that may be associated with adaptation to tropical conditions (Table 7.2).

7.4 Examples of African Indigenous Chicken Breeds

Most poultry in Africa are chickens, ducks, and other species. Africa is home to various local and exotic chickens. The various chicken and duck breeds were introduced from the Southeast Asian region and adapted to the African conditions for thousands of years. In this and the next section, we present information on chicken breeds according to the regions of Africa. It should be noted that information regarding the indigenous chickens of Africa is limited. Most of the information is only available (DAD-IS n.d.).

7.4.1 Chicken Breeds in North Africa

A few indigenous chicken breeds in North Africa are characterized and studied. Although most indigenous chicken breeds are nondescript, some show morphological differences; they may be considered breeds or ecotypes (Negash et al. 2023). Such breeds as Fayoumi (Egypt), which is adapted to North Africa's harsh and dry conditions, can be used in future breed improvement programs. Descriptions of significant North African indigenous chickens are given below.

Table 7.1 Identified characteristics of some African indigenous chicken breeds

Country	Local name	Identifiable characteristics	Mature male weight (kg.)	Mature Female weight (kg.)	References
Burkina Faso (DAD-IS n.d.)	Cou nu, Joub-kole	Na: naked neck F: frizzle	1.5	1.2	DAD-IS (n.d.)
Chad (DAD-IS n.d.)	Chicken of Moulkou	P: pea comb	1.5	1	DAD-IS (n.d.)
Chad (DAD-IS n.d.)	Dijded	P: pea comb	1.5–2.0	1.0–1.5	DAD-IS (n.d.)
Ghana (DAD-IS n.d.)	Local Ghanaian	Na: naked neck, F: frizzle, P: pea comb	1.2	1.1	DAD-IS (n.d.)
Lesotho (DAD-IS n.d.)	Basotho	P: pea comb	1.8	1.6	DAD-IS (n.d.)
South Africa (DAD-IS n.d.)	Kaalnekke	Na: naked neck	–	–	DAD-IS (n.d.)
Swaziland (DAD-IS n.d.)	Inkhukhu	Na: naked neck	2.1	1.6	DAD-IS (n.d.)
Sudan (DAD-IS n.d.)	Large balady	Na: naked neck	–	–	DAD-IS (n.d.)
Ethiopia (DAD-IS n.d.)	Melata	Na: naked neck	–	–	DAD-IS (n.d.)
Cameroon (DAD-IS n.d.)	Sudano–Sahelian, Forest zone chicken, Northwest/West chicken	Na: naked neck F: frizzle C: Crested S: feathered shanks, T: feathered tarsus, N: normal feathered	1.4–1.7	1.2–1.3	

Table 7.2 Examples of genes in indigenous chicken populations that may be linked to the adaptation to tropical conditions

Gene	Mode of inheritance	Direct effects	Indirect effects
Dw: Dwarf	Recessive, sex-linked, multiple allele	Reduction of body size between 30 and 10% from the normal size	Reduced metabolism, improved fitness, disease tolerance
Na: Naked neck	Incomplete dominant	Loss of neck feathers, reduction of pteryla width, reduction of secondary feathers	Improved ability for convection, reduced embryonic livability (hatchability), improved adult fitness
F: Frizzle	Incomplete dominant	Curling of feathers, reduced feathering	Decreased fitness under temperate conditions, improved ability for convection
K: Slow feathering	Dominant, sex-linked, multiple allelic	Delay of feathering	Reduced protein requirement, reduced fat deposition during juvenile life, increased heat loss during early growth
Id: Non-inhibitor	Recessive, sex-linked, multiple allelic	Dermal melanin deposition in the skin and shanks	Improved ability for radiation from shanks and skin
Fm: Fibro-melanosis	Dominant with multifactorial modifiers	Melanin deposition all over the body, sheaths of muscles and nerves, and blood vessel walls	Protection of skin against UV radiation, improved radiation from the skin, increased packed cell volume, and plasma protein
P: Pea comb	Dominant	Change of skin structure, compact comb size, reduction of pterylae width, development of breast ridges	Decreased frequency of breast blisters, sex limited, improvement of late juvenile growth

Source: Horst (1989b)

7.4.1.1 Beheri

Distribution and Population Statistics: The breed originated in the Northern region and the Delta of Egypt with an estimated population size of 800,000 (DAD-IS n.d.).

Physical Characteristics: Detailed description of the breed is unavailable; however, the average body weight of mature Beheri chicken weighs 1.7 and 1.3 kg for the cocks and hens, respectively.

Adaptive and Special Genetic Characteristics: Beheri chickens are resistant to leukosis and spirochetosis, have high fertility (more than 95%), and are early maturing for cocks (4.5 months) and hens (5 months).

Typical Production Systems, Husbandry Practices, and Production Characteristics: Information regarding the production system, husbandry practices, and production characteristics is unavailable. However, being an adaptive local chicken, the Beheri chicken would suit low-input and low-output production conditions.

7.4.1.2 Dandarawi

Distribution and Population Statistics: Dandarawy is an indigenous chicken from Egypt, genetically the closest to the other Egyptian ecotypes (Sabry et al. 2021). According to (DAD-IS n.d.), Dandarawi is a locally adapted breed with an estimated population of 20,000.

Physical Characteristics: The cocks are heavier than the hens, with an average body weight of 1.7 kg (cocks) and 1.2 kg (hens). Hens are pinkish with white breast feathers and a Colombian pattern, with black markings on the neck, wing, and tail.

Adaptive and Special Genetic Characteristics: Like Beheri chickens, they have high fertility (95%). Hens are also good layers with 185 eggs/hen/year. They mature early at the average age of 4.5–5 months for the cocks and hens, respectively.

Typical Production Systems, Husbandry Practices, and Production Characteristics: Information regarding the production system is unavailable; however, being early maturing and good layers, they must be suitable for environments where ideal management conditions are challenging.

7.4.1.3 Dokki-4

Distribution and Population Statistics: Dokki-4 is a cross between Fayoumi and Barred Plymouth Rock with an estimated population of 20,000 (DAD-IS n.d.). It is developed in Egypt.

Physical Characteristics: Being crossbred, the average body weight for cocks and hens is 2.4 and 1.7 kg, respectively. Adult birds have blue plumage; neck feathers are silvery-white and red ear lobes; day-old chicks have grayish-brown stripes.

Adaptive and Special Genetic Characteristics: No unique, adaptive, bad, or special genetic characteristics were reported. However, Dokki-4 is a crossbred expected to perform better with many adaptation qualities from Fayoumi.

Typical Production Systems, Husbandry Practices, and Production Characteristics: Dokki-4, although not reported, is expected to suit the smallholder to semi-commercial production systems.

7.4.1.4 Fayoumi (Fig. 7.1)

Distribution and Population Statistics: Fayoumi breed originated in the Fayoum Province of Egypt (Hossaryl and Galal 1994).

Physical Characteristics: The cocks and hens weigh 2.2 and 1.6 kg, respectively. Fayoumi chickens resemble the silver Campine breed in body shape and plumage color.

Adaptive and Special Genetic Characteristics: Fayoumi chickens mature early cocks (5 months) and hens (5.5 months). They are fertile (95%) and produce 205 eggs/hen/annually on average. They lay eggs of good shell quality and a high percentage of yolk/albumin. They also resist such diseases as spirochetosis and leukosis.

Typical Production Systems, Husbandry Practices, and Production Characteristics: Fayoumi chickens are widespread in the tropics, where the temperature is high. Reports

Fig. 7.1 Fayoumi chicken. (Courtesy Dr. Wondmeneh Esatu)

show their suitability for smallholder poultry production systems.

7.4.1.5 Gimmizah

Distribution and Population Statistics: Gimmizah is a crossbred between the White Plymouth Rock and Dokki-4 (Galal 2007). It is considered a local chicken of Egypt.

Physical Characteristics: The average body weight for the cocks and hens is 2.2 kg and 1.6 kg, respectively.

Adaptive and Special Genetic Characteristics: Identification of chick sexing is possible for this breed at day old. They reach sexual maturity at 5.5 and 6 months for the cocks and hens, respectively. They lay, on average, 195 eggs annually. The breed resembles the Barred Plymouth Rock in its shape and color. The feathers are light gray and are barred with a darker gray. The Gimmizah showed an improvement in the local breeds in their productive and reproductive abilities.

Typical Production Systems, Husbandry Practices, and Production Characteristics: Detailed information regarding the production system is scarce.

7.4.1.6 Alaraby

Distribution and Population Statistics: Alaraby is distributed in the West and South of Libya. According to (DAD-IS n.d.), it has an estimated population of 50,000.

Physical Characteristics: They have yellow skin color, single comb type, red and black plumage color, gray shank, and feet. Hens lay cream, white, or pale grayish eggs. The average body weight of mature chickens is 1.9 kg for cocks and 1.9 kg for hens.

Adaptive and Special Genetic Characteristics: Alaraby chickens resist heat and diseases and adapt to dry and poor environments. The age at the first egg for hens is 6.6 months, and they lay 138 eggs annually.

Typical Production Systems, Husbandry Practices, and Production Characteristics: The Alaraby chickens are a good option for smallholder production conditions and can survive by scavenging available feed resources.

7.4.1.7 Moroccan Beldi

Distribution and Population Statistics: Moroccan Beldi (Beldi meaning "native" in Arabic) is an indigenous breed population with an estimated population of one million. The Beldi chicken is raised in rural areas of the Khenifra Region of Morocco.

Physical Characteristics: Beldi chickens have large phenotypic variability. They appear in black, brown, gray, and white colors, pure or mixed. Sexual maturity is 154 days for roosters and 168 days for hens in chickens. The age at first egg averaged 5.8 months for hens. The number of eggs laid per hen per year was 78 for the hens with a hatchability rate of 78%. The chickens weigh 1.9 kg (male) and 1.5 kg (female).

Adaptive and Special Genetic Characteristics: No adaptive and unique genetic characteristics were reported. However, being a chicken from drier areas, they may possess the ability to withstand harsh environments.

Typical Production Systems, Husbandry Practices, and Production Characteristics: The Moroccan Beldi can be a good chicken

for drier areas of the tropics, where feed supply can be challenging.

7.4.1.8 Large Sudanese Baladi

Distribution and Population Statistics: Sudanese native chicken breed is one of the main ecotypes (Yousif and Eltayeb 2011).

Physical Characteristics: The average body weight for cocks and hens is 1.9 kg and 1.4 kg, respectively.

Adaptive and Special Genetic Characteristics: Large Sudanese Baladi is a hardy breed, able to thrive under very harsh conditions; on average, hens mature late (8 months) and lay 50 eggs annually.

Typical Production Systems, Husbandry Practices, and Production Characteristics: Large Sudanese Baladi chickens can be kept under smallholder production conditions in drier areas.

7.4.1.9 Sudanese Bare Neck Baladi

Distribution and Population Statistics: Estimated population of 1,000,000 (DAD-IS n.d.).

Physical Characteristics: The chickens are naked neck, with an average body weight of 1.1 kg in hens, and they lay on average 106 eggs annually and are an important local chicken in Sudan (Binda et al. 2012).

Adaptive and Special Genetic Characteristics: Being naked neck, they exhibit adaptation to heat stress.

Typical Production Systems, Husbandry Practices, and Production Characteristics: They can produce in areas of high heat stress.

7.4.2 West and Central Africa

Various colors and conformations phenotypically characterize local chickens in West Africa. Despite this phenotypic diversity, West African local chickens have many traits in common with wild chicken populations (Guisso et al. 2022). Their local adaptation calls for conservation and utilization strategies.

7.4.2.1 Naine

Distribution and Population Statistics: Naine is an indigenous breed from Burkina Faso with a small population of 10,000 (DAD-IS n.d.).

Physical Characteristics: They are lightweight, with an average of 1.1 kg cocks and 0.8 kg hens. Sometimes they exhibit frizzle feathers.

Adaptive and Special Genetic Characteristics: The average age of maturity for cocks and hens is seven and 6 months, respectively. The hens lay 60 eggs per year.

Typical Production Systems, Husbandry Practices, and Production Characteristics: With frizzle feathers and light body weight, Naine is suitable for harsh hot environments where feed supply is challenging.

7.4.2.2 Naked Neck

Distribution and Population Statistics: This is an indigenous breed, southern and central Burkina Faso, with an estimated population of 10,000 (DAD-IS n.d.).

Physical Characteristics: The average body weight for cocks and hens is 1.5 kg and 1.2 kg, respectively. The flock exhibits both naked-necked and frizzled feathers. The average age of maturity for both cocks and hens is 6 months. Hens produce 60 eggs annually.

Adaptive and Special Genetic Characteristics: They are resistant and tolerant to some diseases like mycoplasmosis, pseudo avian plaque, and pasteurellosis. They show remarkable thermotolerance.

Typical Production Systems, Husbandry Practices, and Production Characteristics: They are suitable for harsher and drier areas of the tropics.

7.4.2.3 Souche Kondé

Distribution and Population Statistics: The origin of this strain is not known, but it is widely available in southern Burkina Faso.

Physical Characteristics: Both the cocks and hens are heavy, with the average weight for males and females of 2.5 kg and 1.5 kg, respectively. They mature at 6 months. Hens produce 60 eggs annually.

Adaptive and Special Genetic Characteristics: No unique qualities were reported.

Typical Production Systems, Husbandry Practices, and Production Characteristics: Although information regarding the production system is unavailable, they are a good candidate for a smallholder production system.

7.4.2.4 Ghanian Fowl

Distribution and Population Statistics: This is an indigenous chicken widely present in Ghana; the estimated population size is about four million (DAD-IS n.d.).

Physical Characteristics: Most of the local chickens are usually feathered (96%), with a small proportion of naked neck (2%) and frizzled (2%). The average body weight for cocks and hens is 1.2 kg and 1.1 kg, respectively.

Adaptive and Special Genetic Characteristics: Local chickens are disease-tolerant and excellent scavengers. The hens are broody all year round, start egg laying at 5.5 months, and lay 150 eggs annually.

Typical Production Systems, Husbandry Practices, and Production Characteristics: As good scavengers, disease-tolerant, and good mothers, the local chickens of Ghana are suitable for smallholder production conditions.

7.4.2.5 Poule De Benna

Distribution and Population Statistics: This is an indigenous chicken found in the Region Du Benna of Guinea. According to (DAD-IS n.d.), the population is estimated to be 10,000.

Physical Characteristics: Poule De Benna is a big chicken with long shanks, a naked neck, and black eyes. Both cocks and hens weigh, on average, 2.3 kg.

Adaptive and Special Genetic Characteristics: Poule De Benna chickens are resistant to Newcastle disease. The hens are very broody, start egg laying at 6.5 months, and produce 80 eggs per year.

Typical Production Systems, Husbandry Practices, and Production Characteristics: Poule De Benna are suitable for smallholder poultry production systems.

7.4.2.6 Poule du Guinea

Distribution and Population Statistics: An indigenous chicken from Guinea with a population of 15 million (DAD-IS n.d.).

Physical Characteristics: These chickens are variable in size but short beaks and single combs are dominant; they are multicolored, but red, white, and black are dominant. The average body weight of mature chickens is 1.5 kg for cocks and 1 kg for hens.

Adaptive and Special Genetic Characteristics: Hens have a robust brooding instinct and produce, on average, 60 eggs per annum.

Typical Production Systems, Husbandry Practices, and Production Characteristics: These chickens are suitable for the village poultry production system.

7.4.2.7 Nigerian Normal Feathered Chicken

Distribution and Population Statistics: Might have originated from the junglefowl of Java and the Indonesian islands. It is distributed throughout Nigeria.

Physical Characteristics: The hens, on average, weigh 1.07 kg. The hens start egg laying at 25 weeks. With five clutches, they produce 180 eggs per year, weighing 23–38 g.

Adaptive and Special Genetic Characteristics: No unique characteristics were reported.

Typical Production Systems, Husbandry Practices, and Production Characteristics: As most indigenous chickens, the chickens can be kept in village management conditions.

7.4.2.8 Poule du Sénégal

Distribution and Population Statistics: This is an indigenous breed distributed throughout Senegal. According to (DAD-IS n.d.), the estimated population size is about 29 million.

Physical Characteristics: Poule du Sénégal are small, rustic birds usually uni-colored (light brown or white). The Senegal chicken varies in color, but the most frequent colors are brown (13.8%), white (12.4%), yellowish (8.4%), white and brown (8.4%), and light brown (7.8%) (Missohou et al. 1998). The

cocks weigh 1.5 kg, the hens 1 kg. Hens lay 60 eggs annually.

Adaptive and Special Genetic Characteristics: Small size, rustic bird, unicolored. Hens have 3–4 egg laying cycles per year, laying between 6 and 15 eggs per cycle.

Typical Production Systems, Husbandry Practices, and Production Characteristics: Chickens are reared by all ethnic groups in Senegal.

7.4.2.9 Cameroon Chicken

Distribution and Population Statistics: Cameroon national poultry flock was estimated at 35 million, 70% being indigenous chickens (Fotsa et al. 2011).

Physical Characteristics: Males average 1.4–1.7 kg, while females average 1.2–1.3 kg.

Adaptive and Special Genetic Characteristics: Across all agro-ecological zones, the presence of genes for naked neck, frizzle, normal feathered, feathered shanks, crested, and rose comb is indicated.

Typical Production Systems, Husbandry Practices, and Production Characteristics: In all the agro-ecological zones, family/backyard production systems are the norm.

7.4.3 Eastern Africa

Local chicken in East Africa shows extensive phenotypic diversity. Chickens appeared in the region relatively late, around ~700 BC, with their geographic origin remaining unknown, with the Indian subcontinent, Southeast Asia, and North Africa as possible primary centers of origin (R.I.U 2012). Local chickens in East Africa are found across the entire region and in all agro-ecological zones; they show large within-population phenotypic diversity in plumage color, feather morphology, pattern, skin color, comb type, etc. (Msoffe et al. 2001; Dana et al. 2010).. Large maternal genetic diversity in the region could potentially support genetic improvement programs (Mwacharo et al. 2013).

Fig. 7.2 Horro chicken. (Courtesy Dr. Wondmeneh Esatu)

7.4.3.1 Horro (Fig. 7.2)

Distribution and Population Statistics: Indigenous breed, Oromia regional state in western Ethiopia, Horro is an indigenous chicken type named after the geographic region of origin, located in the western part of Ethiopia near the Blue Nile gorge. There are about 30,000 chickens restricted to this original environment (DAD-IS).

Physical Characteristics: Horro chickens are predominantly brown, and hens lay about 178 eggs annually that weigh 52–58 grams. They also have crests.

Adaptive and Special Genetic Characteristics: Horro chickens are hardy and resist diseases.

Typical Production Systems, Husbandry Practices, and Production Characteristics: Horro chickens are suitable for smallholder poultry production systems. They are good scavengers and excellent mothers.

Fig. 7.3 Konso chicken. (Source: Dana et al. 2010), Food and Agricultural Organization, reproduced with permission)

7.4.3.2 Konso (Fig. 7.3)

Distribution and Population Statistics: Konso chickens are indigenous chickens found in the Southern Region of Ethiopia.

Physical Characteristics: Adult cocks weigh about 1.4 kg and hens 1.0 kg; most cocks have red body plumage, whereas brown, zigrima, and black are the prominent plumage colors in hens. Both white and yellow skin colors exist. The shape of the head is mainly flat (DAD-IS n.d.).

Adaptive and Special Genetic Characteristics: No unique features were reported.

Typical Production Systems, Husbandry Practices, and Production Characteristics: Reared under scavenging management. Konso chickens are suitable for smallholder/village poultry production conditions.

7.4.3.3 Mandura

Distribution and Population Statistics: The breed is available in the western part of Ethiopia in Benshangul Gumuz regional state, with a small population size of 21,000 (DAD-IS n.d.).

Physical Characteristics: Brown is the most predominant plumage, and complete red is typical of cocks but absent in hens. Almost all chickens have normal feather distribution. The average shank length of adult males is 8.4 cm, and that of females is 7.1 cm; adult cocks weigh about 1.6 kg, and hens 1.4 kg.

Adaptive and Special Genetic Characteristics: No unique features were reported.

Typical Production Systems, Husbandry Practices, and Production Characteristics: As the breed adapted to the drier areas of western Ethiopia, where feed supply is a challenge.

7.4.3.4 Tepi (Fig. 7.4)

Distribution and Population Statistics is an indigenous breed adapted to the southwestern parts of Ethiopia.

Physical Characteristics: The population of the breed is estimated to be about 50,000 (DAD-IS n.d.).

Adaptive and Special Genetic Characteristics: No unique features were reported.

Typical Production Systems, Husbandry Practices, and Production Characteristics: The breed can suit village or smallholder poultry production conditions.

7.4.3.5 Tililli (Fig. 7.5)

Distribution and Population Statistics: An indigenous breed that originated from and is widely spread in the Sekela areas of Ethiopia near the source of the Blue Nile (DAD-IS n.d.).

Physical Characteristics: This ecotype is known for its better growth and egg production (1.2 kg and 147 eggs/hen/year).

Adaptive and Special Genetic Characteristics: No unique features were reported.

Typical Production Systems, Husbandry Practices, and Characteristics: Suit smallholder poultry production systems.

7.4.3.6 Kenyan Chicken

Distribution and Population Statistics: Kenyan chicken is an indigenous breed adapted to rural and peri-urban areas of the country, with an estimated population of about 33 million (DAD-IS n.d.).

Fig. 7.4 Tepi chicken. (Courtesy: Dr. Wondmeneh Esatu)

Fig. 7.5 Tilili chicken. (Courtesy: Dr. Wondmeneh Esatu)

Physical Characteristics: Average body weight for cocks and hens is 2.2 kg and 1.6 kg, respectively. No unique pattern within the feather, yellow skin color, single comb type, various plumage colors, various shank and foot colors, cream white to pale grayish eggshell color.

Adaptive and Special Genetic Characteristics: No unique features were reported.

Typical Production Systems, Husbandry Practices, and Characteristics: They are suitable for smallholder poultry production systems.

7.4.3.7 Rwandan Chicken

Distribution and Population Statistics: Indigenous breed from Rwanda.

Physical Characteristics: Rwandan indigenous chickens have four comb types (strawberry—most dominant, whiteness of earlobes, rounded ear lobe shape, and curved beaks), varied beak color (green, black, yellow, and brown), evenly distributed feathers (most common), and naked-neck phenotypes (this was rare, occurring in about 0.2% of chickens), brown eyes, yellow-colored thick skins, and yellow-colored shanks (Fig. 7.6). The chickens are small and rustic and produce 50 eggs annually.

Adaptive and Special Genetic Characteristics: No unique features have been reported.

Typical Production Systems, Husbandry Practices, and Characteristics: The breed can suit village or smallholder poultry production condition.

7.4.3.8 Ugandan Chicken (Fig. 7.7)

Distribution and Population Statistics: This is an indigenous chicken breed widely distributed in the eastern and northern regions of Uganda. The population is estimated to be more than 22 million (DAD-IS n.d.).

Physical Characteristics: Both the cocks and hens are heavy, with an average body weight of 4 and 2 kg for females and males, respectively. The hens show five clutches of 10–12 eggs.

Adaptive and Special Genetic Characteristics: No unique features were reported.

Typical Production Systems, Husbandry Practices, and Characteristics: The breed can suit village or smallholder poultry production condition.

Fig. 7.7 Ugandan chicken. (Source: Yussif et al. 2023) (Licensed under C-C By 4:0)

Fig. 7.8 Ovambo. (Source: Grobbelaar et al. 2010, Food and Agricultural Organization, reproduced with permission)

7.4.4 Southern Africa

South African domestic chickens are a significant bird genetic resource, and more conservation efforts are being made to save these unique genotypes. South African chickens are the result of multiple introductions and dispersion, with their high genetic diversity potentially originating from China, Southeast Asia, and the Indian subcontinent (Mtileni et al. 2011).

7.4.4.1 Ovambo (Fig. 7.8)

Distribution and Population Statistics: The population is small and limited to 10,000.

Physical Characteristics: Dark in color and small in body size.

Adaptive and Special Genetic Characteristics: Very aggressive and agile and can catch and eat mice and young rats. Can fly and roost on the top of trees to avoid predators.

Typical Production Systems, Husbandry Practices, and Production Characteristics: Scavenging and semi-scavenging chicken production system.

7.4.4.2 Potchefstroom Koekoek (Fig. 7.9)

Distribution and Population Statistics: Northwest Province and Gauteng Province of South Africa (DAD-IS n.d.).

Fig. 7.9 Potchefstroom Koekoek chicken. (Courtesy: Dr. Wondmeneh Esatu)

Physical Characteristics: Average height for cocks and hens 2.51 kg and 1.7 cm, respectively; light and dark gray with a white barred pattern within the feather (barred, sex-linked), skin color (yellow), comb type (single), plumage color (gray and white), shank and foot color (yellow), eggshell color (light brown). The average age at the first egg for a hen is 4.27 months, body weight at the hatch for both sexes is 35 g, and annual egg production is 196 eggs.

Adaptive and Special Genetic Characteristics: The breed has a specific resistance or tolerance to poultry diseases, adaptability to cold and heat, wet and drought, high egg production, brooding well, and the ability to hatch their offspring.

Typical Production Systems, Husbandry Practices, and Production Characteristics: Scavenging and semi-scavenging chicken production system.

7.4.4.3 Venda (Fig. 7.10)

Distribution and Population Statistics: Discovered in Limpopo province, Vhembe, and Capricorn district, and other parts of Gauteng, Mpumalanga, Free State Province, of South Africa, with a small population of 10,000 (DAD-IS).

Physical Characteristics: The average body weight for cocks and hens is 2 and 1.9 kg, respectively. They have a single comb type and lay cream white to a pale grayish egg.

Fig. 7.10 Venda chicken. (Source: Grobbelaar et al. 2010, Food and Agricultural Organization, reproduced with permission)

Adaptive and Special Genetic Characteristics: Ability to fly away from predators and to roost in the tree, resistance or tolerance to diseases and parasites, adaptability to the high temperate area and harsh environment, good quality egg production, brooding, and good mothering instincts. Hens lay, on average, 153 eggs annually (Grobbelaar et al. 2010).

7.4.4.4 Boschveld (Fig. 7.11)

Typical Production Systems, Husbandry Practices, and Production Characteristics: The breed suits village or backyard production conditions. They are good scavengers too.

7.5 Local and Exotic Duck Breeds in Africa: Characteristics, Distribution, and Features

7.5.1 Indigenous and Exotic Duck Breeds of North Africa

Duck breeds in North Africa are limited in numbers and almost entirely imported from abroad. They are less popular as compared to chickens

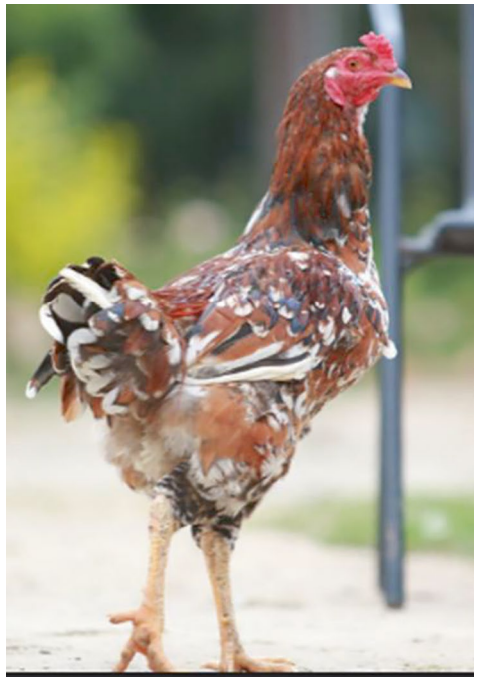

Fig. 7.11 Boschveld chicken. (Source: http://boschveld.co.za/)

that are widely kept. Below, the description of duck strains is given.

7.5.1.1 Domiati

Distribution: Domiati is widely distributed in the north of Egypt (DAD-IS n.d.).

Physical Characteristics: Females are small.

Adaptive and Special Genetic Characteristics: No unique features were reported.

Typical Production Systems, Husbandry Practices, and Production Characteristics: Information regarding the production system is not available.

7.5.1.2 Pekin

Distribution and Population Statistics: It is an imported breed into the lower Egypt and delta regions (DAD-IS n.d.).

Physical Characteristics: The plumage is creamy white; the legs and feet are a yellowish orange. The beak is yellow, short, and almost straight.

Adaptive and Special Genetic Characteristics: Disease resistance, good adaptation to local conditions, and known for its hardiness.

Typical Production Systems, Husbandry Practices, and Production Characteristics: Raised at the commercial and village levels.

7.5.2 West and Central Africa

7.5.2.1 Ghanaian Duck

Distribution and Population Statistics: This is an indigenous breed with a country-wide distribution. The estimated population size is 200,000 (DAD-IS n.d.).

Physical Characteristics: Average body weight for cocks and hens is 2.4 and 1.7 kg, respectively.

Adaptive and Special Genetic Characteristics: Resistant to various diseases, the average age of maturity for hens is 6 months, and they lay about 60 eggs per year.

Typical Production Systems, Husbandry Practices, and Production Characteristics: They are raised in smallholder production conditions.

7.5.3 Eastern Africa

7.5.3.1 Albet

Distribution and Population Statistics: Gambella and Benishangul regions of Ethiopia (DAD-IS n.d.).

Physical Characteristics: White and black colors are dominant, and they lay 57 eggs annually.

Adaptive and Special Genetic Characteristics: No unique features were reported.

Typical Production Systems, Husbandry Practices, and Production Characteristics: They can be raised in smallholder production conditions.

7.5.3.2 Ugandan Duck

Distribution and Population Statistics: Crossbreeds of the original Muscovy ducks imported from Britain (DAD-IS n.d.). They

are distributed throughout Uganda, especially in urban and peri-urban areas, with an estimated population of about a million.

Physical Characteristics: Large bird with an average body weight for cocks and hens is 10 and 6 kg, respectively.

Adaptive and Special Genetic Characteristics: No unique features were reported.

Typical Production Systems, Husbandry Practices, and Production Characteristics: They are raised scavenging feed resources available in the household and backyards.

7.5.4 Southern Africa

7.5.4.1 Aylesbury

Distribution and Population Statistics: Aylesbury is imported and locally adapted to all agro-ecological zones of Zambia (DAD-IS n.d.).

Physical Characteristics: The Aylesbury duck is a breed of domesticated duck, bred mainly for its meat and appearance. It is a large duck with pure white plumage, orange legs, and feet. On average, the body weight of cocks and hens is 4.5 and 4 kg, respectively. They are unicolored (white).

Adaptive and Special Genetic Characteristics: No unique features were reported.

Typical Production Systems, Husbandry Practices, and Production Characteristics: Can be raised under smallholder production conditions.

7.5.4.2 Madada

Distribution and Population Statistics: This is an indigenous breed from Zambia with an estimated population of 100,000 (DAD-IS n.d.).

Physical Characteristics: Average weight for cocks and hens is 2.5 and 1.8 kg, respectively.

Adaptive and Special Genetic Characteristics: This breed resists most duck diseases. The hens mature at the age of 6 months and produce 40 eggs per year.

Typical Production Systems, Husbandry Practices, and Production Characteristics: Can be raised under smallholder production conditions.

7.6 Exotic Chicken Breeds in Africa

Introduction Although not well developed, the poultry sector in Eastern African countries has grown from a backyard poultry-keeping operation to a more commercial-oriented system (Vernooji et al. 2018). However, the introduction of exotic genetics into smallholder-intensive chicken production has yet to prove competitive in sub-Saharan Africa because of management issues and high costs of feed, veterinary, and energy inputs (Tabler et al. 2023). Africa's leading countries in chicken meat production are Algeria, Egypt, Morocco, South Africa, and Nigeria (DAD-IS n.d.), which mainly depend on chicken strains. The broiler chicken strains include Arbor Acres, Cobb 500, Cobb 700, Ross, and Ross Indian River. The layer chicken breeds are Hy-Line Brown, Hy-Line Silver Brown, ISA Brown, ISA White, Lohmann Brown, Lohmann Silver, and Lohmann White. Breeds such as white and brown Leghorns, Rhode Island Red, New Hampshire, Cornish, Australorp, and Light Sussex were crossed with local chickens to improve the genetic potential of indigenous breeds (Dana et al. 2011).

Physical Characteristics The exotic African chicken breeds originated from combining different worldwide chicken strains. Most of the inputs to develop are dual-purpose chicken strains, such as Rhode Island Red and white leghorn. Mostly, the broilers are white in color and heavy in body weight, while the layers are either white in the white egg layer or brown in the case of the brown egg layer. Layers are generally small to medium-sized.

Adaptive and Special Genetic Characteristics The commercial chickens, layers, and broilers are meant for improved management conditions where good management and

proper feeding, health, and housing are provided. Such strains have been less efficient in Africa as the breeds lack adaptation traits for harsh environments. There are efficient feed converters (broilers) or layers (laying hens).

Typical Production Systems, Husbandry Practices, and Production Characteristics The standard production system for such chicken strains and commercial management conditions; however, farmers in Africa keep them with less sophisticated management conditions. The broiler birds attain 2–2.5 kg live weight at 6–7 weeks and are ready for the market, while layer birds reach 16 weeks before the pullets start laying eggs. The average industry egg production is 230–250 eggs/layer/year (Kusi et al. 2015). Most of the exotic chicken breeds introduced into Africa are commercially mainly kept and managed by medium to big farms.

7.7 The Importance and Role of Poultry for Smallholders

Most of the poultry population in Africa exists in villages with low-input, low-output systems (Guèye 2000; Gilbert et al. 2015). Although large-scale commercially produced poultry products are available, the indigenous chicken remains vital (Wondmeneh 2015), as an example of food sovereignty, where communities prefer a sustainable production system that supplies healthy, culturally appropriate food (Patel 2009; Wong et al. 2017). African consumers prefer eggs and chicken meat from indigenous stocks to those derived from commercial flocks of imported ones, and they, therefore, fetch premium prices (Gueye 2009). Rural poultry supply 70–90% of poultry products in Africa (Alabi et al. 2006; Branckaert and Guèye 2000; Kitalyi 1998; Mack et al. 2005); income from poultry products is often the primary source of income for female-headed households. In contrast, male-headed families usually have multiple income sources and even take over the poultry business when they realize financial feasibility (Aklilu et al. 2008; Muchadeyi et al. 2004). Small-scale poultry production systems have been integrated with human livelihoods for thousands of years, enhancing the rural poor's diet, income, and food and nutrition security (Alders and Pym 2009). The potential contributions and impacts of extensive, small-scale scavenging poultry production systems in rural, resource-poor areas differ significantly from more intensive systems in urbanized settings (Wong et al. 2017). Poultry in Africa has several roles. Some of the roles have direct economic implications, while others have more social implications. Below are some detailed important roles of poultry production in Africa, namely, contribution to food security, income generation and employment, GDP contribution, and sociocultural.

(a) *Role in Food Security*: Food security remains a severe challenge for many households in Africa (Silvestri et al. 2015). Mild to moderate protein-energy malnutrition is common throughout the developing world, which contributes to poor growth, diminished mental development, and *illness* in children (Neumann et al. 2002). Animal source foods address malnutrition by supplying the essential nutrients that are lacking in plant-sourced foods, such as micronutrients like iron, zinc, vitamin B-12, riboflavin, and conjugated linoleic acids (Ndlovu 2010). Farmers in rural areas have better access to poultry products as compared to others. Poultry contributes 20–32% of total animal protein intake (Tadelle et al. 2003; Kitalyi 1998).

(b) *Roles in Income Generation and Employment*: Increasingly, with the impact of climate change, including on crop productivity, farmers need to look for alternative sources of income (Vermeulen et al. 2012). Chickens can adapt to drier areas with the potential to cope with feed shortages. A scavenging chicken produces eggs with little or no supplementation. Few eggs can be collected and sold to the local markets to support the family income, to meet some basic needs, such as buying clothes for children or for meeting some financial obligations of learners in school. Women have better access to the income from chicken, although men take

over with better prospects of income from poultry. Poultry can serve as an income-generating activity, providing sustainable employment for rural households (Pica-Ciamarra and Otte 2010). The better the level of inputs used, the higher the production will become. The need for better interventions, such as tropically adapted and yet productive chicken strains and supporting packages, might be the first step to transforming the existing system.

(c) *Roles in GDP Contribution*: The economic contribution of poultry at a household level cannot be overlooked. The sector employs 80–85% of the population and contributes 40% to the total GDP. Rural chicken in Ethiopia represents a significant part of the national economy in general and the rural economy and contributes to 98.5% and 99.2% of the national egg and chicken meat production, respectively (Asresie et al. 2015). Apart from that, poultry in villages serves as disposable cash at any need and is named poor men's "ATM" (Pal et al. 2020). The ability of the live product to be 'stored' for a more extended period is a unique characteristic. Regardless of its enormous impact, the actual contribution of the village poultry to the national GDP is barely quantified. Considering the size of the population keeping village chickens, the contribution to the national GDP is significant.

(d) *Roles in Sociocultural Issues*: Apart from the monetary and food terms, poultry in Africa has other functions. The sociocultural importance of poultry is age-old. Keeping poultry by village communities throughout Africa has been practiced for many generations. More than 85% of rural families in sub-Saharan Africa support some poultry species. For example, approximately three chickens for every two people (Gueye 2009). In addition to providing farmers with eggs and meat for their home consumption, poultry products' sale (or swap) enables poultry keepers to obtain money to spend on their own and family specific needs. Moreover, poultry is symbolic in many social activities and religious ceremonies (Akinola and Essien 2011). In Zimbabwe, the preferred taste of chicken meat is available and reserved for special guests or ceremonial gatherings (weddings or funerals) (Muchadeyi et al. 2004). In Kenya, chickens are helpful in several social, cultural, and spiritual activities such as entertainment, gifts, funeral rites, and spiritual cleansing (Magothe et al. 2012b).

7.8 Indigenous Poultry Breeds Conservation Efforts and Biobanking in Africa

A speedy and constant decline in animal species populations has been recognized in recent years (IUCN 2010). The chicken genetic resources are the most endangered and under-conserved (Hoffmann 2009). At the global level, more than 1600 local chicken breeds have been identified; 33% are considered endangered to critical breeds, and another 40% have unknown risk status (FAO 2007). The 126 indigenous breeds recognized for Africa are most often generalized under the name of local chicken despite their great variability and specific traits (DAGRIS 2021). These breeds contain vast ranges of phenotypic and genetic diversity resulting from the diversity of environmental and human selection pressures. Regrettably, many of these local breeds are classified as at risk due to the introduction and adoption of exotic breeds, acceptance of intensive chicken production systems, changes in the environment, disease conditions, and adverse development policies. The conservation of African indigenous poultry breeds is vital in light of their rapid loss through commercial dilution and breed replacement. All varieties of these breeds are important candidates for conservation. While in situ in vivo conservation strategies are highly relevant to conserving diversity, other complementary conservation strategies, such as germplasm cryopreservation, are needed not only to conserve unique adaptations and gene combinations but also to be able to respond to the needs of future generations. To

reduce this genetic erosion, it is crucial to improve knowledge of local breeds and production systems, improve planning, and raise awareness of the threat at the policy level. New innovations in genetic preservation technologies for chickens are also needed. All African indigenous chicken populations with economic potential, scientific use, and cultural or aesthetic interest should be part of the conservation efforts.

7.8.1 Conservation Efforts of Indigenous Poultry Breeds in Africa

Conservation of poultry genetic resources engages numerous activities, including strategies, management, planning, policies, and effective actions, intended to ascertain that the diversity of the genetic resource is maintained to contribute to current and future agricultural and food production (Rege and Gibson 2003). Conservation of genetic resources encompasses characterization, identification, monitoring, and utilization to ensure management for the best short-term use and longer-term availability (Moyo 1995). The economic framework for the sustainable use and conservation of animal genetic resources, including poultry, is outlined in Chap. 25.

7.8.1.1 In Situ Conservation Programs

In African countries, there has been little effort to conserve the local chicken breeds or lines (Manyelo et al. 2010). It is alleged that 33% of indigenous chicken breeds are facing extinction (FAO 2007; Manyelo et al. 2010). Most poultry genetic resources are conserved in situ in the living populations, which are facing. The challenges of epidemics and climate (Assan 2015). In situ conservation programs for indigenous chickens in Africa mostly involve various individual smallholder farmers and farmers associations. Unfortunately, this category of custodians is not benefiting from enough support for their contribution to the conservation effort.

7.8.1.2 Ex Situ Conservation Programs

In vivo ex situ conservation of chickens is mainly practiced by breeding and dissemination centers, held by national research institutions, universities, and industrial poultry farms, as important reservoirs of indigenous chicken biodiversity through the collection of frozen semen. These are generally targeted poultry populations collected from their natural environment and transferred to breeding centers for research or development purposes. Ex situ protection programs may have some sustainability challenges in Africa. Most often, they may be coupled to cryopreservation and reproduction technologies for the conservation and dissemination. These introduce the aspects of biotechnology applications and the need for gene banks as biorepositories where representative samples of genetic resources are preserved. This should be supported by data banks where metadata related to the attributes of breeds are stored in a systematic way. The technological advancement of poultry reproductive technologies and precision breeding provides insight into ex situ conservation as it facilitates the capture of the entire genetic makeup of the populations.

7.8.2 Poultry Germplasm Biobanking in Africa

African poultry germplasm is a live information source for all the genes present in the African indigenous poultry breeds, which can be conserved for long periods and regenerated whenever required in the future. The conservation of these genetic resources through cryopreservation, referred to as biobanking, is an important component for the conservation and revival of rare or endangered species. Germplasm cryobanking, or cryoconservation, is the most successful method to conserve the genetic traits of endangered and commercially valuable species. Germplasm cryobanking involves the harvesting and freezing of gametes, embryos, gonadal tissues, somatic tissues, or PGCs of species threatened with extinction. There is considerable diversity in the cryobiological conditions among cell types and tissues of each species. Research

done by scientists from the Centre for Tropical Livestock Genetics and Health (CTLGH) at the Roslin Institute, University of Edinburgh, has focused on developing techniques for the conservation and recovery of the genetic material of chickens. This is an attractive complement to the indispensable maintenance of genetic diversity through living animals. However, research is needed to effectively apply these techniques in a multidisciplinary program aimed at the preservation of the numerous subpopulations of animals that exist within a given species. Previously, it has not been possible to biobank chicken genetic material, but the recent innovation at the Centre for Tropical Livestock Genetics and Health (CTLGH) and International Livestock Research Institute (ILRI) using Primordial Germ Cells (PGCs) has changed that. There is now a way forward to preserve the future biodiversity of African poultry breeds.

7.8.3 Biobanking Using Stem Cell Techniques

Cryopreservation of stem cells is valuable to offer storage of high cell numbers, fast transport, and to preserve cells for long periods. Due to the increased level of endangered poultry breeds, it is important to preserve genetic material for future applications. Conservation of poultry breeds and genetic lines poses challenges. Most poultry genetic resources are maintained in situ in living populations. However, this conservation approach of genetic resources always carries the risk of losing the population owing to pathogen outbreaks, genetic problems, breeding cessation, and/or natural disasters. Biobanking, whereby sperm, eggs, or zygotes are conserved, is the ex situ alternative. Common in mammalian species, the approach does not work well for avian species in females due to the large amount of lipid deposited in the oocyte (Petitte 2006; Whyte and McGrew 2015). Other genetic preservation and propagation techniques, such as cloning using somatic cell nuclear transfer, are not possible because embryo transfer cannot be done in avian species (Kjelland et al. 2014). Cryobanking of germplasm in birds has been mainly limited so far to the use of semen.

7.8.3.1 Primordial Germ Cells (PGCs) Technique

As an alternative, avian primordial germ cells (precursor cells for gametes, which temporally circulate in the vasculature during early development) can be incorporated into the gonads (Yasuda et al. 1992) and differentiated into functional gametes following transplantation to recipient embryos (Tajima et al. 1993; Ono et al. 1998). An avian PGC transplantation technique has been established and is readily available now at ILRI. To date, several techniques for PGC manipulation, including purification, cryopreservation, depletion, and long-term culture, have been developed in chickens. PGC transplantation combined with recent advanced PGC manipulation techniques has enabled ex situ conservation of poultry genetic resources in their complete form. In collaboration with AU-IBAR, the poultry PGC technologies for conservation have been introduced to African NARS scientists and are ready for deployment.

7.8.3.2 Induced Pluripotent Stem Cells (iPSCs) and Mesenchymal Stem Cells (MSCs) Techniques

Induced pluripotent stem cells (iPSCs) are somatic cells reprogrammed by ectopic expression of transcription factors or small molecule treatment, which resemble embryonic stem cells (ESCs) (Zhang et al. 2014). They represent a great promise for conserving and generating genetically improved and locally adapted poultry genetic resources. Numerous reports emphasize the importance of chicken iPSCs as well as MSCs for their self-renewal potential and multilineage differentiation as well as current knowledge concerning their usefulness for conservation, various biological properties and health studies, and the use of MSCs as a feeder layer or as a very promising tool for immunomodulatory cell therapy in immune-mediated diseases (Zhao et al. 2016). Hence, stem cells beyond conservation purposes provide a useful model in the field of chicken biological studies.

7.9 Chicken Production Systems

Chickens in Africa are in different management and production systems. Most classifications follow the breed type, input and output level, mortality rate, type of producer, production purpose, length of broodiness, growth rate, and number of chickens reared. There are four poultry production systems in the world, as identified (FAO 2014; Alders et al. 2018). For producers to benefit from the poultry production systems and continue to ensure positive and sustainable contributions, production and marketing should be tailored to local conditions and important value chain nodes while maintaining genetic diversity (Table 7.3).

7.10 Chicken Breed Improvement Programs in Africa

Breeding programs for chickens started several decades ago in the tropics. Most attempts were to improve the production performance of local chickens with better adaptation, but with poor production potential. The most common approach was to consider crossbreeding in the form of a cockerel exchange scheme and the direct intro-

Table 7.3 FAO chicken production systems classification

Criteria	Small-extensive scavenging	Extensive scavenging	Semi-intensive	Small-scale intensive
Production/farming system	Mixed, poultry, and crops, often landless	Mixed, livestock, and crops	Usually poultry only	Poultry only
Other livestock raised	Rarely	Usually	Sometimes	No
Flock size	1–5 adult birds	5–50 adult birds	50–200 adult birds	>200 broilers
				>100 layers
Poultry breeds	Local	Local or crossbred	Commercial, crossbred, or local	Commercial
Source of new chicks	Natural incubation	Natural incubation	Commercial day-old chicks or natural incubation	Commercial day-old chicks or pullets
Feed source	Scavenging; almost no supplementation	Scavenging; occasional supplementation	Scavenging; regular supplementation	Commercial balanced ration
Poultry housing	Seldom; usually made from local materials or kept in the house	Sometimes; usually made from local materials	Yes; conventional materials; houses of variable quality	Yes; conventional materials; good-quality houses
Access to veterinary services and veterinary pharmaceuticals	Rarely	Sometimes	Yes	Yes
Mortality	Very high, >70%	Very high, >70%	Medium to high, 20–>50%	Low to medium <20%
Access to reliable electricity supply	No	No	Yes	Yes
Existence of conventional cold chain	No	Rarely	Yes	Yes
Access to urban markets	Rarely	No, or indirect	Yes	Yes
Products	Live birds, meat	Live birds, meat, eggs	Live birds, meat, eggs	Live birds, meat, eggs
Time devoted each day to poultry management	<30 min	<1 h	>1 h	>1 h

Cameroon	Northwest (IRZ 1986)	Local and composite	Dual

duction of exotic chicken strains. As exotic chickens could not survive in African settings and required continuous importation, countries have focused on developing their chicken strains using locally available chickens. The need for better management practices is also a problem. In recent years, new breeding programs (see Sect. 7.1.3) are now bearing fruit. The table below shows some of the successful chicken breed improvement programs in Africa. It is good to note that more programs have yet to be reported (Table 7.4).

7.11 Challenges and Opportunities of Chicken Production in Africa

Poultry production in tropical countries is based on the traditional scavenging system. The share of family poultry to the total poultry population in developing countries in Africa is estimated to reach 70–80% (Sonaiya 1990; Gueye 1998; Sonaiya et al. 1999).

7.11.1 Diseases and Predations

Estimates show that about 60% of chicks die before 8 weeks. Incidence of mortality continues at significant rates even during adult stages. A considerable proportion of loss in adult birds is associated with diseases, although losses due to predators also contributed substantially (Gueye 1998). The significant challenges related to an infection at the producer household level include farmers' inadequate knowledge and awareness of better health care practices and insufficient veterinary services.

7.11.2 Improved Genetics

Poor productivity of local breeds and lack of access to productive and adaptable chicken breeds are the other most critical challenges to increasing the economic contribution of the sub-sector. Most of the chickens kept by smallholder farmers are unimproved indigenous flocks with slow growth rates and poor egg productivity (Sonaiya et al. 1999). Attempts to increase the productivity of the sub-sector are mainly focused on introducing high-yielding exotic chickens to replace indigenous stocks, which have generally failed due to the failure of imported breeds to adapt to local conditions. On the other hand, efforts to develop productive species adaptive to local circumstances have borne fruit in recent years (Wondmeneh 2015). Crossbreeding selected local breeds with selected exotic breeds could produce adapted and productive breeds.

7.11.3 Feeds and Nutrition

The backyard or village chicken production system, the leading practice in Africa, mainly depends on a scavenging feed resource base (SFRB) that is minimally supplemented with household feed scraps. The availability and quality of the scavenging feed resources are highly seasonal, and the carrying capacity of the SFRB can only support a minimal number of chickens (Sonaiya et al. 2002). Similarly, feed, accounting for about 70% of the production cost of commercial chicken meat and egg production, could be supplied more and of better quality. Apart from that, the price of imported items such as premixes and locally produced central feed raw materials such as maize and soyabean is exceptionally high due to the inadequate supply of these grains (Negash 2020).

7.11.4 Training and Extension Support

Lack of awareness and knowledge of smallholder producers on modern chicken production practices is another critical challenge to backyard chicken production.

7.11.5 Institutional Constraints

The development of the chicken sector should be viewed in the context of addressing the entire value chain. Engaging and mobilizing the multiple arrays of actors, both public and private, involved in the value chain is critical to address the many issues involved in developing the sector, such as marketing, delivery of inputs, provision of services and credit facilities, and building capacities of research and relevant development institutions, etc.

7.12 Economic Contribution of Chickens in Africa

Village chickens make substantial contributions to household food security throughout the developing world. Indigenous chickens serve as an investment and source of security for households in addition to their use as sources of meat and eggs for consumption and income (Muchadeyi et al. 2007). Chicken production can be regarded as an investment, contributing to the welfare of women and children in traditional, low-input farming systems in the tropics. According to Ref. (Dana et al. 2010), an average flock of five adult chickens helped women in Central Tanzania to have an additional income equivalent to 10% of the average annual income. In the Niger Delta family, poultry husbandry contributes 35% of household women's income, representing about 25% of the Nigerian minimum wage and 50% of the per capita income (Alabi et al. 2006). Village poultry can be used as an effective means of empowering women and as a tool for poverty alleviation. Experiences in many other developing countries have been reported (Kitalyi 1998).

7.13 Implication and Ways Forward

Poultry production in Africa and beyond is an essential source of food, income, and employment. The African poultry sector is so underdeveloped that the demand for poultry products still needs to be met. Previous interventions by governments and nongovernmental organizations have not been fully applied. The introduction of exotic blood into the harsh environment cannot be successful. The problems involve the threat to the existence of the local chicken that the farmers heavily depend on. Future interventions should work on the balance: the need for more meat, eggs, and income on one side and the utilization of local and exotic chicken in appropriate breed combinations coupled with animal recording.

The plans should start with knowing what Africa has and strategically approaching the problem.

7.14 Conclusion

An extensive indigenous poultry conservation and biobanking program will not only support research and development to prevent problems with inbreeding and preserve at-risk poultry breeds but also reduce the large number of live animals needed to be kept for research across the world. It could also have an important role within poultry breeding companies to maintain important parental lines of mainstream poultry breeds used in commercial poultry production without the need to keep large populations of live birds. It is important to note that more work needs to be undertaken, and it should be government policy to encourage the conservation of these breeds to avoid extinction. Therefore, conservation strategies and genetic improvement can be developed and implemented simultaneously in a coordinated approach. This strategy will allow new progeny to be developed and studied while the original breed is preserved.

Pig Genetic Resources of Africa

8

Richard Osei-Amponsah and Wilson S. Kaumbata

Abstract

The African pig genetic resource is valuable for food security, income generation, and livelihood sustenance, as well as for sociocultural and religious activities. This chapter highlights the unique adaptive and resilient attributes of the indigenous pig breeds found in various regions of Africa and makes a case for their sustainable improvement, use, and conservation. The first section (Sect. 8.1) highlights the advantages of pigs over other livestock species and the key roles pigs play in enhancing the livelihoods of both rural and urban farmers across the African Continent. The origins, domestication, and classification of pigs, including dispersal to various parts of Africa and their subsequent development into distinct western, eastern, and southern African pig breeds, are detailed in Sects. 8.2, 8.3, and 8.4. Distribution of pigs to North African countries is scanty due to sociocultural and religious restrictions. Sections 8.5 and 8.6 provide information on various pig production systems practiced in rural and urban settings, including the status of existence and implementation of various pig improvement programs across the continent. The sections further highlight status and challenges relating to the conservation of indigenous pigs, considering the proliferation of exotic breeds and prevalence of uncontrolled mating and unregulated crossbreeding, particularly in rural settings where the free-range pig production system dominates. The chapter concludes by presenting general challenges faced by pig farmers in Africa, the existence of opportunities, and possible solutions, including strategies that can be implemented to enhance pig production and profitability in smallholder farms.

8.1 Introduction

The pig industry in Africa is a major source of meat, income, employment, and livelihood support. The pig (*Sus scrofa*) is among the few animals with the ability to convert byproducts that would have gone waste from the agricultural industry and households into high-quality animal proteins. Pig production is important to many smallholder livestock farmers, particularly in sub-Saharan Africa. Their relatively short generation interval, high fecundity, early maturity, prolificacy, ability to survive in a wide range of environments and on a variety of feed resources, feed conversion efficiency, as well as their relatively good carcass production relative to ruminants, are comparative advantages for pig producers. Pigs contribute to the animal protein food security of many households in Africa and are a source of wealth creation, particularly for women and the youth. In rural settings where banking services are unavailable, pigs play the role of an inflation-proof cash reserve used by pig farmers during emergencies or when extra cash is needed to meet critical household needs. In most African communities, pigs also play valuable roles in various sociocultural practices, including their use as gifts, payment for dowries, and pork for special dishes during festivities.

Unfortunately, the development of the African pig sector has, over the years, been hindered by several constraints; namely: inadequate and poor nutrition, poor animal healthcare, relatively low production potential of the indigenous pig, and unfavorable policy and institutional environment. A sustainable pig industry, however, will require national governments to invest in the capacity of stakeholders in the pig industry and promote multistakeholder public-private partnerships at all levels (FAO et al. 2017). An important requirement to achieve this objective is the development and implementation of appropriate livestock policies to support stakeholder activity along the pig value chain. Furthermore, knowledge of pig farmers on biosecurity should be regularly updated to help prevent infectious disease outbreaks, including African Swine Fever (ASF). This will motivate them to adopt appropriate, practical, and affordable technologies for sustainable biosecurity in small-scale free-ranging pig production system (FAO et al. 2017). Over the years, a lack of adequate support in pig farming has constrained the growth of the industry and negatively impacted local producers. It is therefore important for national governments and other stakeholders to increase investments in this regard to improve farmers' livelihoods and food security. In line with these, the objective of this chapter is to synthesize available information on *Sus* genetic resources in Africa (indigenous and locally adapted exotic breeds), pig production systems, sustainable use, and conservation of pig genetic resources for wealth creation and food security, as well as the challenges of the pig value chain and the opportunities they present for sustainable improvement of the African pig genetic resources.

8.2 Origin, Domestication, and Classification of African Pigs

8.2.1 Origin and Domestication of African Pig

Pigs are believed to have been first domesticated roughly over 40,000 years ago, making them one of the earliest animals domesticated by humans. The origins of African domestic pig breeds are

unclear, poorly documented, and shrouded in controversy due to insufficient archaeological and genetic evidence to establish sound hypotheses about how, when, and where the *Sus* species were founded (FAO 2007a; Amills et al. 2013; Ramirez et al. 2009; Weka et al. 2020) on the continent. Available archaeological evidence from the Middle East indicates that pigs were domesticated as early as 9000 years ago, when most livestock were utilized by nomadic people, while swine were utilized by settled farming communities (Weka et al. 2020; Motsa'a et al. 2021). Other research findings (Amills et al. 2013; Halimani et al. 2020) indicate that indigenous African pigs originated from the Iberian Peninsula between the third and seventh centuries, with most of the present-day populations having similar phenotypic characteristics in all African countries, but referred to by different local and often tribal names. For example, the African indigenous pig is known in South Africa as Kolbroek, in Mali as Somo, in Kenya as Busia pig, in Cameroon as Bakosi, in Nigeria as the Local/Black pig, in Ghana as the Ashanti Dwarf pig, in Togo as Bush pig, in Zimbabwe as Mukota pig, and in Mozambique at the Landim (Amills et al. 2013; Halimani et al. 2020).

It is also believed that the African pig was domesticated following the introduction of Asian and/or European pigs through commercial trade routes (Sowls 1984). This was further substantiated by genetic studies on the local populations of African indigenous pig breeds. One study by Ramirez and colleagues (2009) showed that North and West African pig breeds have significant European ancestry, which may be in line with Portuguese exploration in the fifteenth century. Other archaeological findings posit that the contemporary Eastern African pig breeds' ancestry could have either been by direct introgression with Far Eastern breeds or through a European intermediary, since the earlier British breeds were shown to have carried some Eastern alleles (Weka et al. 2020). As highlighted in Fig. 8.1, archaeological records and molecular studies strongly support Europe (Region 3), the Middle (Region 5), and the Far East (Regions 9 and 10) as the major centers of ancient pig domestication. The ancestry of the indigenous African pigs probably originated from these centers, because this is yet to be confirmed by scientific evidence.

8.2.2 Classification of Pigs

Pigs are omnivores, and their food range is close to that of humans. In fact, between pigs and humans, there are so many significant similarities that pigs are used as experimental models for human medical research (Sykes 2022) and for the production of organs for human health purposes (xenotransplantation) (Montgomery et al. 2022). The pig is one of the oldest domesticated animals, and the majority of the breeds are known to have descended from the Eurasian Wild Boar (*Sus scrofa*) (Weka et al. 2020; Larson et al. 2005). An independent domestication of both European and Asian subspecies of the wild boar has been clearly established (Giuffra et al. 2000). Pigs are classified as follows (Giuffra et al. 2000):

Kingdom	*Animalia*
Phylum	*Chordata*
Sub-phylum	*Craniata* (Vertebrata)
Class	*Mammalia*
Sub-class	*Theria* (Viviparous)
Infra-class	*Eutheria* (Placenta)
Order	*Ungulata* (hoofed mammals)
Sub-order	*Artiodactyla* (even toed)
Sub-division	*Sunia*
Family	*Suidae* (domesticated pigs)
Genus	*Sus*

Pigs are the species that make up the family *Suidae* are known to have originated in Old World Europe, Africa, and Asia. New World pigs, such as the peccaries, differ from true pigs in certain skeletal and dental features and belong to a different family (*Tayassuidae*). A peccary is a medium-sized, pig-like ungulate found throughout Central and South America, Trinidad in the Caribbean, and in the southern deserts of America. The phylogenetic relationships of 19 species in the family Suidae are depicted in Fig. 8.2 and include the following (Larson et al. 2005; Chen et al. 2007):

8.2.3 Dispersal and Genetic Diversity of African Pigs

Pigs are omnivores and have survived in a variety of habitats, including grasslands, rainforests, wetlands, scrublands, temperate forests, and savannas, everywhere in the world except Antarctica, Northern Africa, and far northern Eurasia. It is generally acknowledged that livestock species were incorporated into diversified subsistence economies that utilized a range of domestic, managed, and free-living plant and animal resources. Thus, the movement of both cattle and swine down the eastern and western arms of the Fertile Crescent was slow, with no domestication evidence detected in the southernmost reaches of the Fertile Crescent until about 2000 years after their initial domestication. The poor performance of pigs in this dispersal story, usually coming in either a distant fourth after cattle and caprines in the pastoral economy of Anatolia and Europe, or, as in Africa, generally absent, may also have some relationship to their biological attributes. Higher water requirements

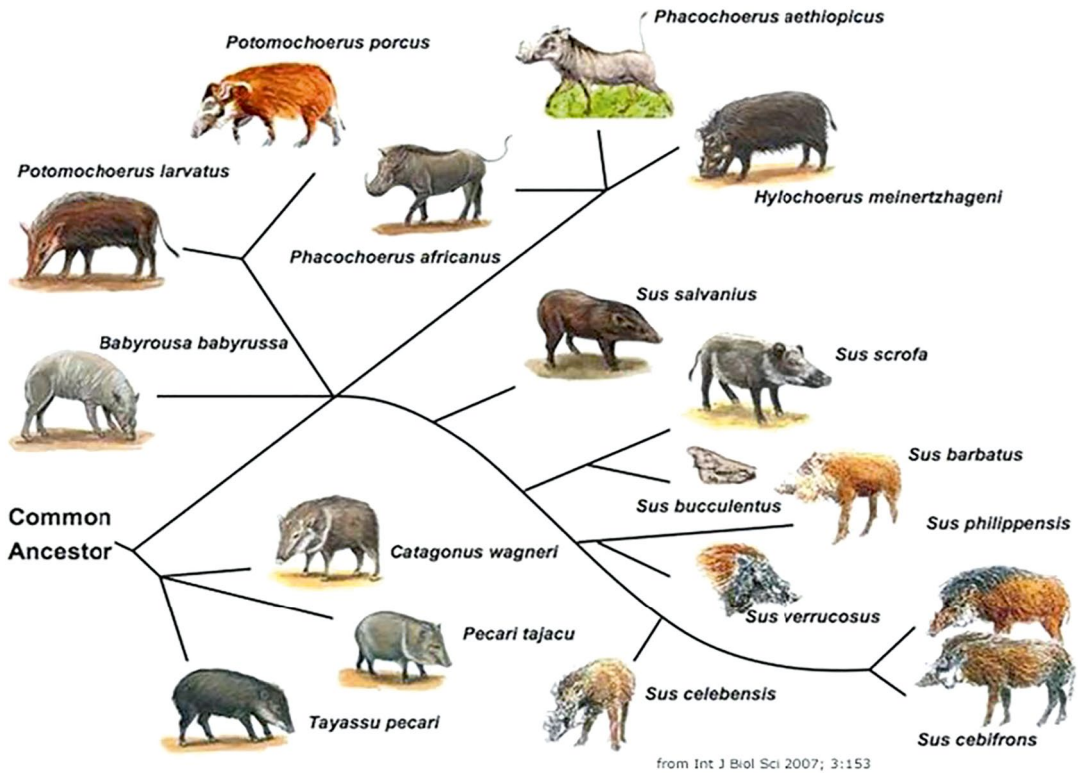

Fig. 8.2 Suiforme diversity and phylogenetic relationship. (From Chen et al. 2007, licensed under CC-BY 4.0). (Source: https://untamedscience.com/family/suidae/)

and the fact that pigs are temperamentally ill-suited to long-distance transhumance (Zeder 2017) may well have played an important role in shaping their dispersal story.

The genetic diversity of African pigs indicates how close or how different the various Sus genetic resources on the continent are. In general, the relationship between the African indigenous pigs and their ancestors has not been elucidated or studied extensively like that of the European and Far Eastern pig breeds (Amills et al. 2010; Ramirez et al. 2009). undertook the first genetic survey of a number of pig breeds distributed in Western (Nigeria and Benin) and Eastern (Kenya and Zimbabwe) Africa but did not find any close relationship between the Near Eastern wild boars and African pigs, which is opposed to reported close relationships between Near Eastern and European *S. scrofa* populations and Near Eastern wild boars (Weka et al. 2020; Larson et al. 2005). Resolution of the genetic make-up of the African pig breeds has also revealed substantial differences between Western and Eastern African populations. The West African pigs share some alleles that are abundant in European breeds, while eastern and southern African breeds harbor Far Eastern alleles at very high frequencies (Ramirez et al. 2009). Two alternative scenarios might explain the presence of Far Eastern alleles in East African pig breeds. First, they might have been introduced through either a European intermediary, given that British pig breeds were strongly admixed with Chinese genotypes in the eighteenth–nineteenth centuries, and second, there might have been a direct genetic introgression with Far Eastern breeds. These findings are probably because 79% of African pigs analyzed with microsatellites were originally from East Africa, where the Far Eastern introgression has been particularly strong (Ramirez et al. 2009; Halimani et al. 2020). In Western Africa, pigs do not display Far Eastern alleles, suggesting that

they descended from the admixture of indigenous populations and exotic breeds with European ancestry (i.e., Iberian pigs brought by the Portuguese in the fifteenth century as well as swine introduced by the European colonizers in the nineteenth–twentieth centuries). In strong contrast, Eastern African pigs harbor Far Eastern alleles at significant frequencies, evidencing that they have a mixed European/Chinese origin (Ramirez et al. 2009; Amills et al. 2010). At the same time, archaeological records have shown that the indigenous African pig breeds, typified by the ADP of Ghana, Kolbroek of South Africa, and the Bakosi of Cameroon and Gabon, probably originated from the Iberian region (Weka et al. 2020; Halimani et al. 2020).

In reference to the first strategic priority area of the Global Plan of Action (GPA) on Animal Genetic Resources (AnGR) (FAO 2007b), not much research has been done on the characterization of African indigenous pig breeds. While the African Union Inter-African Bureau for Animal Resources (AU-IBAR) has developed a tool and portal for characterization of the continent's animal genetic resources, there has been very little commitment by most national governments to allocate resources for activities directed toward boosting both human and institutional capacity for sustainable use and conservation of Africa's rich AnGR (AUIBAR 2019). Available data on pig characterization depicts inadequate research coverage of the populations and countries, or largely fragmented studies that are not well coordinated. There is thus an urgent need for adequate characterization of indigenous African pig breeds for informed decisions on mapping their distributions, population status, diversity, and sustainable utilization (Giuffra et al. 2000; Bester and Küsel 1998).

8.3 The Importance and Use of Pig Genetic Resources in Africa

Madmizure et al. (2013) list some of the uses of pigs as provision of meat, income generation, sociocultural values, savings and investment, family pride/status, and manure. Indeed, African indigenous pig breeds are of great agricultural and food security importance, uniquely adapted to the existing production systems and environments, and possess resilient traits for their survival. Although pigs are raised as homestead animals to provide food for the household, most pig farmers also raise pigs mainly as a source of income (Aryee et al. 2019). For instance, one study in Central Ethiopia found that farmers did not slaughter pigs for home consumption but mainly kept them as a source of income (Gebrehawariat et al. 2017). The majority of pig farmers interviewed in Ghana kept crossbred pigs with income as their main motivation (Aryee et al. 2019). Pig production in Africa is thus of economic, nutritional, and sociocultural importance to livelihoods (Aryee et al. 2019). Regardless of the social and religious restrictions that exist in certain African communities, pig farming is playing an important role in tackling poverty, malnutrition, and a deficit in animal protein, thanks to its numerous advantages. Due to its low production cost, fast growth rate, and short cycle, pig farming has been recommended as an alternative source of cheap, high-quality dietary protein for the escalating human population (Motsa'a et al. 2021).

Indigenous pigs utilize feedstuffs of low nutritive value, are thermotolerant, are resistant to certain diseases and parasites, and can survive and reproduce in low-input and resource-limited systems. However, due to their slow growth rates and small body sizes, the productivity of indigenous pig breeds is low and not able to cope with increased pork demand in most African countries. To satisfy the surging demand for pork and pork products, national governments have often resorted to the importation of high-producing exotic pig breeds, mostly from Europe and America. Dotché et al. (2019) provide extensive information on the reproductive performance of local breeds of pigs, such as age at puberty, gestation length, litter size at birth, litter size at weaning, birth weight, weaning weight, and age at weaning, recorded in some African countries. It should be stressed that these performance parameters are affected by many environmental factors, including feeding, the breeding program, and

greatly improved by crossbreeding with exotic breeds using artificial insemination.

These exotic pig breeds have existed alongside the local African breeds for decades and have been naturalized in different environments of Africa. However, the commercial exotic and the native African pig breeds and their crossbreds exist in distinct production systems and play key roles in African animal agriculture. The commercial exotic breeds dominate in medium and large-scale intensive farms. The medium-scale intensive farms are commonly found in and around urban and peri-urban environs of major cities with good markets for pork and pork products. Different actors play various roles along the pig value chain, creating employment and livelihoods for millions of people in the process. Processing, sale, and consumption of pork is commonplace in many African countries such as Burkina Faso, Ghana, Nigeria, Uganda, Kenya, Tanzania, and Cameroon. Compared to chicken meat and beef, pork is relatively cheaper for most consumers.

Not surprisingly, there has been a fast growth in the number of actors in the pig value chain, with a resultant growth in the pig sector estimated at between 5% and 10% annually (FAO et al. 2017). Pig production has been an attractive venture to an increasing number of smallholder rural farmers in Africa. It is estimated that over 70% of the pig output in African countries comes from smallholder rural pig farms. The indigenous African pig breeds and their crossbreds with exotic breeds dominate in these farms. The relatively short production cycle of the *Sus* species, their prolificacy and ability to survive on a wide range of feeds, as well as high carcass are key motivators for their production. In a rural setting where banking services are unavailable, pigs play the role of an inflation-proof cash reserve to be used during emergencies or when extra cash is needed to meet household needs (Aryee et al. 2019).

8.4 Pig Breeds of Africa

Africa boasts a rich diversity of indigenous and locally adapted exotic pig genetic resources and their crosses, which have been a great source of animal protein, support of livelihoods, wealth, and sociocultural values over the years. African indigenous pig breeds display varying phenotypic and adaptive characteristics (Osei-Amponsah et al. 2017). The AU-IBAR (2019) describes indigenous African pigs as small, dark-colored animals with small ears, a short forehead, a straight tail, and an elongated snout. The body is often narrow, carried on relatively long legs. Coat color is variable and sometimes covered with long, coarse hairs and a distinct mane along the spine. They may vary in size, but adult pigs rarely weigh above 60 kg. The pigs are generally adapted to low-input systems practiced in many rural areas of Africa and other developing countries. Generally, the indigenous African pig breed has relatively good adaptive traits, such as tolerance to endemic diseases and survival under poor management, including heat stress, and it is also able to handle fibrous feeds much better than exotic breeds. Sample indigenous pig breeds include Kolbroek (South Africa), Somo (Mali), Busia (Kenya), Bakosi (Cameroon and Gabon), West African Dwarf pig (Nigeria), ADP (Ghana), Bush pig (Togo), Mukota (Zimbabwe), and Tswana (Botswana) (Halimani et al. 2020). In some countries, the indigenous pigs have no specific names but are generally referred to as local, indigenous, or forest pigs, and these may also refer to crossbreds or admixed populations. However, the breed status of most *Sus* breeds on the continent remains unknown, and literature on most of the indigenous breeds remains largely unavailable. Therefore, in the subsequent sections, we document as much available information as possible on indigenous and locally adapted exotic pig breeds on the African continent with emphasis on their unique adaptive traits and the production environments that promote their conservation and sustainable use.

8.4.1 Geographical Distribution of African Pig Breeds

In terms of numbers, a total of 43,007,434 pigs are found in Africa, with 28,914 in North Africa, 15,678,263 in West Africa, 8,139,402 in Central Africa, 17,649,551 in Eastern Africa, and 1,511,304 in Southern Africa in the year 2021 (FAOSTAT 2022). In terms of number of breeds, Southern Africa has the highest number of pig breeds (64), followed by Western Africa (34), Central Africa (24), and Eastern Africa (23), with Northern Africa reporting just a single breed from Egypt due to sociocultural and religious reasons (AUIBAR 2019). According to the Food and Agricultural Organization (FAO) Domestic Animal Diversity Information System (DAD-IS) database (Food and Agriculture Organisation of the United Nations (FAO) 2020) (https://www.fao.org/dad-is/en/) and FAO country reports, the following *Sus* Genetic Resources are commonly found in various regions of Africa (Table 8.1).

8.4.2 Pig Breeds of North Africa

Although pigs are not common in North Africa, some archaeological data indicate that pigs were bred in Ancient Egypt during the fourth century and dispersed to North and Sub-Saharan Africa through the Nile corridor and subsequently to West, East, and Southern Africa. However, the pig population in North African countries is believed to have been substantially affected by the growth, domination, and expansion of Islam. Although Islam forbids Muslims to eat pork, Muslims living in multireligious communities have tolerated pigs kept by others and have at times utilized pork for magical purposes (Epstein 1971). On the other hand, where Islam is the dominant religion, pig production is forbidden, the cause of the disappearance of the species in most parts of Northern Africa.

Additionally, some religions in ancient Ethiopia and Egypt with strong links to Christian Old Testament teachings prohibited their followers from raising pigs, the reason for the relatively low pig populations in these parts of Africa. Additionally, research on African pigs was for many years also not common on the agenda of the International Livestock Research Institute (ILRI), as well as the fact that the *Sus* species compete with humans for food, and thus, feeding them may be expensive. Collectively, these facts, among others, have also contributed to the scant information on pig breeding and production in Africa. It is believed that pigs were herded, raised, and occasionally eaten throughout Egypt from the Predynastic period into the Late Period and Graeco-Roman times (Parsons 2017). The domestic pig of ancient Egypt descended from an indigenous ancestor, *Sus scrofa*, the Wild Boar. Once abundant in the country with a fairly extensive range throughout the Nile Valley, in the Delta, the Faiyum, and the Wadi Natrun, the pigs only became locally extinct around the turn of the twentieth century, mainly as a result of overhunting, loss of their prime habitat, and the spread of Islam. Indeed, pig remains have been found throughout Egypt at sites such as Hierakonpolis, Maadi, Abydos, and Armant, near graves of the lower social class, indicating that pork was an important component of their diet, particularly during the Predynastic period. If there was a prohibition against eating pigs among the upper classes, there was none against raising them. Pigs' teeth, together with other ingredients, are on record to have been mixed and bandaged onto infected parts of the body to expel exudations, perhaps a reference to pus or eczema. The literature also indicates that pig viscera, including the brain, was an ingredient in a cure to combat cancer (Parsons 2017).

8.4.2.1 Baladi Pig Breed

The FAO's DAD-IS (Food and Agriculture Organisation of the United Nations (FAO) 2020) records only one pig breed in Egypt, called Baladi, which means land or soil. The Baladi is an indigenous pig breed of Egypt (Galal 2007), with a population estimate of more than 300,000 heads. However, very little information is available or has been published on the Baladi pig. Pig farming and consumption is concentrated in Egypt's Coptic Christian minority, estimated at 10% of the population. Pig farms were sited near

garbage pits at the outskirts of cities and were often exposed to poor hygienic production conditions. Local pig breeds like the Baladi were reared in slum areas by rubbish collectors who fed the pigs mainly on leftover feed from the rubbish dumps, and in this way, the pigs help in the disposal of organic waste. Meat from the Baladi is sold in special shops in larger cities to pork consumers (Galal 2007).

8.4.3 Pig Breeds of West Africa

West Africa is home to several indigenous and locally adapted exotic pig genotypes as well as many crossbreds between indigenous and exotic genotypes with different levels of admixture. Like in other parts of Africa, indigenous pig genetic resources are known by various names in the region, such as Somo (Mali), *Porc de Togo* (Togo), West African Dwarf pig (Nigeria), and Ashanti Dwarf Pig (Ghana), also known as the Ashanti Black Forest pig, among others. The origin of indigenous pigs of West Africa is controversial, but recent work on molecular genetic characterization suggests that they harbor alleles similar to pigs in the Middle East and the Far East. West African pig breeds may thus have contributed to the Eastern pig germplasm through trade routes across the Indian Ocean (Amills et al. 2013; Ramirez et al. 2009; Dotché et al. 2019; Osei-Amponsah et al. 2017; Agbokounou et al. 2016).

8.4.3.1 Ashanti Dwarf Pig

The Ashanti Dwarf Pig (ADP), also known as the Ashanti Black Forest Dwarf Pig, is an indigenous breed of Ghana raised at the subsistence level in mixed farming systems. Unlike many local pig breeds in Africa, the ADP has been characterized both at the phenotypic and molecular levels (Osei-Amponsah et al. 2017; Adjei et al. 2015a, b; Aryee 2023). Findings of genetic characterization studies indicate that the Ashanti Dwarf pig has both European and Asian ancestry, with both mitochondrial data and coat color suggesting a stronger contribution from Asian genetics in the north of Ghana (Osei-Amponsah et al. 2017). Black coat color is the most predominant within the ADP, with black MC1R alleles of both Asian and European origin present. European alleles for spotting are present at a low frequency and may account for the occurrence of spotted piglets in some APD litters (Osei-Amponsah et al. 2017). On a global level, the ADP cluster closely with European pigs of commercial origin, but FST (average inbreeding coefficient of subpopulations relative to the total population) analyses identified loci for ADP-specific traits (Osei-Amponsah et al. 2017). Adjei et al (2015a).

reported wide variations in morphological attributes of the ADP population in Ghana. In general, animals classified by owners as ADPs presented a concave head profile (85.9%), black coat color (67.5%), a plain coat color pattern, erect ears (84.7%), projecting backward (52.2%), and a short, cylindrical snout. Although the majority had short and straight body hair type, others had long and dense, or long and curly coats. A few ADPs (15%) had a straight back line, but the majority were swaybacked (85%). Other indigenous pigs in the survey had semi-lop ears, straight head profiles, white and black coat color types, patchy and spotted coat color patterns, and long and cylindrical snouts. It is possible these differences in phenotypes occur owing to genotypic differences in the indigenous swine gene pool, reflecting their admixture, which could potentially dilute highly beneficial adaptive genes. Porter et al. (2016) confirmed some of these findings, indicating that the ADP is usually black (Fig. 8.3) but may also be black pied, brown, or white and occasionally gray. It has a long head, a long tapering snout, upright ears, and quite long legs. Weka et al (2020). describe the ADP as hardy, able to survive under poor management, mostly scavenging for their food, and able to digest high fibrous matter; they are well adapted to resist heat stroke as well as other harsh environmental conditions and are less susceptible to many local diseases and have parasites and one good mothering ability (Weka et al. 2020).

The ADP is tolerant to most common diseases and stressors and can survive under poor management and extreme environmental conditions (Osei-Amponsah et al. 2017; Barnes and Fleischer 1998). Indigenous pigs in general have low production potential but are well adapted to extensive, low-input production systems. On the other hand, exotic breeds require intensive husbandry practices (adequate feeding, improved housing, and regular veterinary care), which many small-scale farmers cannot afford. Indigenous pig breeds like the ADP thus offer a viable alternative for many small-scale local farmers to increase livestock production (Osei-Amponsah et al. 2017). Average mature adult weighs around 40–60 kg, with females reaching an average mature age of 7.5 months and average litter size between 5 and 8 (Weka et al. 2020; Porter et al. 2016). Crosses of ADPs with exotic breeds have generated animals with relatively high growth rates, but their ability to forage on fibrous feed and resistance to diseases are reduced. Thus, despite its relatively low cost of production, the ADP has, over the years, faced the threat of high gene introgression from exotic breeds such as the Large White, Landrace, and Duroc (Osei-Amponsah et al. 2017, 2021).

Fig. 8.3 Ashanti Dwarf pig of Ghana

8.4.3.2 Burkina Faso Pig

In many countries in Africa, the pig breeds are not inventoried and well-defined as breeds. They are regarded as "indigenous or local," or "none improved" pig breeds. The indigenous pig breed of Burkina Faso or Burkina Faso pig (Fig. 8.4) is small in body size, rustic/local of white, black, or mapie and white coat, with very hard silks, and is of great heterogeneity in production. The live weight of adult pigs varies between 40 and 60 kg (Kiendrebeogo et al. 2012). Like most of the local pigs in Africa, information on the phenotypic and molecular characterization of the local pig of Burkina Faso is scant, and there is a need for more research on this breed.

8.4.3.3 Korhogo Pig

The Korhogo breed (pig of Korhogo) is commonly found in Burkina Faso and Cote d'Ivoire.

The Korhogo pig breed started with a cross between the Craonnaise (West French White) pig breed and indigenous female pigs. The best-performing descendants were further crossed with boars of Yorkshire (Large White). The stabilization of these final genotypes in the village of Korhogo in the Republic of Côte d'Ivoire produced the Korhogo pig breed (Fig. 8.5). It is considered a rustic/local and prolific breed, found in all pig production systems in and around Bobo-Dioulasso's area (Kiendrebeogo et al. 2012) of Burkina Faso. The Korhogo breed, like other improved pig breeds such as the Large White, is superior in terms of the number of piglets per litter in all the production systems (Kiendrebeogo et al. 2012) compared to indigenous pig breeds. Information on phenotypic and molecular characterization of the breed is lacking, and this research gap needs to be filled.

8.4.3.4 Liberia Native Pig

The dominant body coat color pattern of the Liberia native pig is solid/uniform/plain (80%), spotted (11%), and patchy/pied (8%) (Karnuah et al. 2018) (Fig. 8.6). In terms of coat color, the pigs were predominantly white (79%) with some pigs being fawn (9%) or black (7%) (Karnuah et al. 2018). The head profile of the Liberia native pig is mostly straight (83%) or concave (16%), and the tails are straight (66%) or curly/kinked (34%) with straight (81%) or swayed back (19%) backline (Karnuah et al. 2018). Information on the molecular characterization of Liberia's local pigs is lacking, and this research gap needs to be filled.

8.4.4 Pig Breeds of Central Africa

As shown in Table 8.1, the Central African region is home to several pig breeds due to the popularity of pig farming in Cameroon, the Central African Republic, Chad, Congo, the Democratic Republic of Congo, and Gabon. Despite the popularity of pigs in this region, information on their phenotypic and molecular characterization remains scarce.

8.4.4.1 Bakosi Pig

A popular indigenous pig breed of Cameroon is the Bakosi (Fig. 8.7), a variety of the West African pig (Iberian in origin), which is black and often with random and quite extensive white patches, and it is like the forest pig of Nigeria and Ghana in size and performance. Phenotypically, the Bakosi pig is of a small size and has a long head with a short, almost flat forehead, a straight muzzle, and an elongated snout. The ears are small, thick, and horizontal or erect. The neck is short, the back slightly convex, and quite long. The croup is sloping, and the ham is sparse. The limbs are slender, not very muscular, with sows having, on average, five pairs of teats. The bristles are long, and the coat color can be black, gray, and red piebald (Mason and Maule 1960). In general, Ghomsi et al. (2022) reports the following mor-

Fig. 8.4 Burkina Faso pig. (From Kiendrebeogo et al. 2012, licensed under CC-BY 4.0)

Fig. 8.5 Korhogo pig of Burkina Faso and Cote d'Ivoire. (From Kiendrebeogo et al. 2012), licensed under CC-BY 4.0)

Fig. 8.6 Pigs in local production systems in Liberia. (**a**) Libera native pig; (**b**) crossbred; (**c**) Exotic breed

phological attributes of indigenous pigs of Cameroon: coat color—black, white, or black and white coat color (68%), plain coat pattern (82%), straight hair (85%), smooth skin (78%), concave head profiles (61%), long and thin snouts (92%), prick ears (82%) projected either upwards (54%) or backward (39%), straight backline (85%), and tails (68%).

Apart from the Bakosi pig, other indigenous pig breeds found in Cameroon include Bamiléké, Kousseri, Bakim, and Mankon Long Nose (the names are linked to different people or places) (Porter et al. 2016; Audrey et al. 2021) (Fig. 8.7). The Mankon Long Nose is said to be more prolific than the others, and it is under a pig improvement program by the Agricultural Research Institute for Development, Mankon Center (https://irad.cm/). Bankim pigs have multiple coat colors and mainly (65%) front-oriented erect ears, teat number ranging from 5 to 7, similar to most indigenous pigs of Africa (Audrey et al. 2021). Like other breeds, information on the molecular characterization of local pig breeds of Cameroon is lacking, and this research gap needs to be filled.

8.4.5 Pig Breeds of East Africa

The genetic diversity of pigs in the East African region has not been fully characterized, and their breed composition has been the subject of considerable speculation (Mujibi et al. 2018). Genetic characterization of indigenous East African pigs in relation to disease susceptibility is important in understanding the genetic deter-

Fig. 8.7 Indigenous pig breeds of Cameroon. (**a**) Mankon long nose; (**b**) Bakosi; (**c**) Bamiléké. (From Motsa'a et al. 2021, licensed under CC-BY 4.0)

minants of disease tolerance, which may impact the design of appropriate control strategies. Limited studies indicate that East African pigs have a complex ancestry, with haplotypes from Asian, Far Eastern, and European pigs all present in certain populations (Mujibi et al. 2018). The application of genome-wide single nucleotide polymorphism (SNP) markers in characterizing the genetic diversity of domestic pigs revealed that local domestic pigs in Kenya are a nonhomogeneous group. The Busia population consisted of admixed pigs of various breeds, while the Homabay population represents pigs that are homogenous and whose composition is significantly different from that of the international commercial breeds (Mujibi et al. 2018).

8.4.5.1 Ugandan Pig

Pig production in Uganda is widespread and appears to be increasing at a high rate. There is limited information on the types of specific breeds and breeding practices in different pig production systems. Pigs in Uganda can be white, black, or black and white (Tatwangire 2014). This contrasts with the black color of local pigs, which are considered to be indigenous. There are no commercial breeding services for pigs in Uganda, and the use of artificial insemination (AI) in pigs remains limited (Tatwangire 2014). The Ugandan pig, or local pig of Uganda (Fig. 8.8), is mainly black in color with some spotting or white patches in crossbreds between local and exotic breeds, resulting from various pig improvement interventions (Babigumira et al. 2021). The body length is medium (60–80 cm), with a big head, prominent face, and tapering snout. The ears are medium to large-sized, tails are long (17–20 cm) (Marshall 2022). In terms of performance, sows have good mothering ability, with average litter sizes of 6–8 piglets, but intensively managed sows have superior litter sizes up to 15 piglets. The Ugandan pig is hardy, can cope with low-quality feed, and high disease burden, especially mange and worms. However, their carcasses are often very fatty. A mature sow weighs between 70 kg and 120 kg, while a mature boar weighs between 100 kg and 150 kg (Marshall 2022). Crossbred sows produced from crosses between the Ugandan pig and exotic breeds such as the Large White or Landrace are suitable for small-scale producers that are not able to provide high standards of housing, healthcare, and feed (Marshall 2022).

8.4.5.2 Tanzanian Pig

According to Mason and Maule (1960) the Tanzanian indigenous pigs are believed to be descendants of earlier introductions by missionaries during the colonial period (Mbaga et al. 2005). More than 90% of these local pigs are found under traditional systems and are an integral part of smallholder farming systems (Mbaga et al. 2003). Pig farming in Tanzania is mainly carried out by smallholder farmers, involving over 500,000 rural households, representing about 22.4% of agricultural households. Most pigs are kept in high-altitude areas, with about 54% of the pigs in the Southern highlands of

Fig. 8.8 Indigenous pig of Uganda. (Ugandan pig). (From Marshall 2022, licensed under CC-BY 4.0)

Tanzania (SHT) regions of Mbeya, Iringa, Rukwa, and Ruvuma. However, a lack of systematic breeding plans, poor husbandry practices, genetic drift, and possibly mutation have led to pigs of varied phenotypes. Coat color of the pigs varies, but are predominantly white (28%), black and white (24%), and solid black (19.8%). The majority (78%) of pigs have droopy ears and are significantly ($p<0.01$) heavier with a longer trunk and increased body length when compared with those with erect ears. Other features include a long and straight face and a short-curled tail (Mbaga et al. 2005). A study undertaken in the Mbeya region showed that the predominant management system practiced is free-ranging and occasionally tethering. The average mature body weights for boars and sows are 57.4 kg and 54 kg, respectively. The overall mean birth weight of 0.9 kg, weaning weight of 10.8 kg, litter size at birth of 6.6 piglets, and litter size at weaning of 4.3 piglets have been reported for the Tanzanian pig (Lekule and Kyvsgaard 2003). Like other local pig breeds, little research work on the molecular characterization of these breeds has been undertaken to identify and provide more information on genes responsible for their adaptation to relatively harsher production environments.

8.4.6 Pig Breeds of Southern Africa

According to FAO's DAD-IS (Food and Agriculture Organisation of the United Nations (FAO) 2020), all the Southern African Development Community (SADC) countries, except the Comoros Islands, have three major international pig breeds (Large White, Landrace, and Duroc) and several indigenous pig breeds. The main attributes of the indigenous breeds are hardiness, foraging ability, heat tolerance, high fertility, good mothering ability, good-quality meat, tolerance to endemic diseases and parasites, and adapted to low management levels (Halimani et al. 2020).

8.4.6.1 Bantu Pig Breed

The Bantu pig (Fig. 8.9) is mostly found in southern Africa. It is generally considered to have been bred from imported pigs from Asia and Europe and is usually small or medium-sized at maturity. Studies at the University of Pretoria found Traces of the Poland China breed and the English breed "Gloucester Old Spot" in numerous litters produced by one male Bantu pig and several Bantu sows. The Bantu is thought to have been developed from early importations of swine from Europe and Asia. The standard body color of the Bantu Pigs is white with black spots, but reddish-tan pigs are also common in the breed. Reddish tan Bantu pigs are born with longitudinal lines similar to the native bush pig, suggesting past breeding with bush pigs (Porter et al. 2016). Bantu Pigs are regarded as very social animals that coexist very well with others once a herd is formed, though the introduction of new females, gilt or sow, can cause males in the herd to become quite agitated (Porter et al. 2016). Bantu pigs pro-

duce, on average, 6–10 piglets in a litter with two to three litters per year. The average weight of a Bantu piglet at birth is about 0.9 kg, and the body weight of an average adult Bantu pig ranges from 95.3 to 99.8 kg. Little research work on the molecular characterization of the Bantu breed has been undertaken to identify genes responsible for their adaptation and production traits.

8.4.6.2 Mukota Pig Breed

Mukota is an indigenous breed found primarily in Zimbabwe. It is also known as the Rhodesian or Zimbabwe Indigenous pig. The Mukota pig predominates in Zimbabwe, and it is also found in some parts of Mozambique and Zambia. Mukota pigs (Fig. 8.10) are believed to have been introduced in the seventeenth century through trade between Europe and China. There are basically two classes of Mukota pigs. One class is short, fat, and has a short snout resembling the Chinese Lard pig, while the other resembles the Windsnyer (Wind cutter) in being long-nosed with a razor back. They are, however, both black in color without any shades or spots. Although the Mukota indigenous pigs are adapted to the local environment, their numbers are declining largely due to livestock production policies that prefer the use of fast-growing imported breeds (Chimonyo and Dzama 2007). Mukota pigs are well known to be hardy and well adapted to the harsh tropical environment in terms of heat stress, disease resistance, and inadequate nutrition. Mukota pigs have a selective advantage to survive and reproduce on a low plane of nutrition. Mukota pigs can easily survive under very unhygienic conditions, testifying to their high disease resistance. These indigenous Zimbabwean pigs show moderate parasite tolerance, greater than the imported or western varieties. Mukota pigs have been shown to be less susceptible to *Ascaris suum,* and their meat is organoleptically more acceptable to the rural people than meat from European breeds. Mukota pigs, which have been demonstrated to adapt to survive under rural low-input production systems, have been shown to exhibit relatively low growth rates, which could be an advantage in that they do not require large amounts of concentrate feeds (Chimonyo and Dzama 2007). Studies provide evidence that Mukota are better able than imported pigs to utilize agricultural byproducts, such as maize cobs. It has been demonstrated that Mukota pigs are able to utilize fibrous feeds and high-tannin red sorghum better than European breeds such as the Large White (Chimonyo and Dzama 2007).

Fig. 8.9 The Bantu pig of South Africa. (Source: Lilongwe University of Agriculture and Natural Resources 2011, licensed under CC-BY 4.0)

8.4.6.3 The Kolbroek Pig

The Kolbroek (Fig. 8.11) is a synthetic breed developed from a variety of breeds in South Africa. Development of the modern Kolbroek began in 1996 at the Agricultural Research Council (ARC), South Africa, under the leadership of Dr. Danie Visser. He and his team started by refining the nearly forgotten old Kolbroek breed and ultimately succeeded in producing a unique, indigenous pig breed. The modern Kolbroek consists of, among others, Windsnyer, Sandveld Red, Tamworth, and Great White genetics. The Kolbroek is a domestic free-range pig found in South Africa (Halimani et al. 2010).

Kolbroek pigs come in a variety of colors, including black with white blotches and brown with gray blotches. The body frame is small and short compared with other pig breeds in South Africa. Distinctive characteristics are a pot belly and a concave face. Weka et al (2020), reports that Kolbroek pigs are short, with prickled ears, a short snout, and a squashed face. A mature Kolbroek weighs about 150 kg, and fares extraordinarily well on a high-fiber diet. The average purebred Kolbroek weaner weighs approximately 8 kg at between 8 and 10 weeks of age. Kolbroeks

Fig. 8.10 The Mukota pig breed of Zimbabwe. (From https://www.petmapz.com/breed/mukota-pig/#, licensed under CC-BY 4.0)

Fig. 8.11 The Kolbroek pig breed of South Africa. (From http://farmersweekly.co.za, licensed under CC-BY 4.0)

fatten up very rapidly, with four-month-olds presenting up to a 35 mm back fat layer over the ideal of 25 mm. Kolbroek meat is naturally marbled, and the carcasses of young pigs are ideal for manufacturing boerewors, salami, prosciutto hams, and a variety of sausages. Like other indigenous pig breeds, it is known for its hardiness, foraging ability, heat tolerance, high fertility, good mothering ability, good quality meat, tolerance to endemic diseases and parasites, and adaptation to low management levels.

8.4.6.4 Indigenous Pigs of Zambia

Like other African countries, pig production remains crucial to the livelihood of farmers in Zambia, and thus, there are policies to support the conservation of local animal genetic resources, including pigs. The indigenous pig breeds of Zambia are the Lusitu and Nsenga, and they originate from Gwembe and Petauke districts, respectively (Abigaba et al. 2022). These two breeds are more adapted to local conditions, constitute 65% of the national pig flock, and are reared by the majority of traditional farmers (65%) in Zambia (Abigaba et al. 2022). Although studies on the characterization of indigenous pigs to a range of harsh rearing conditions (Abigaba et al. 2022) are scanty, when asked about unique traits they prefer in indigenous pigs, 25.9% and 23.8% of farmers indicated disease resistance and fertility as their preferred traits, respectively. Other important traits include meat quality and foraging ability. For instance, the Nsenga pig is one of the breeds that farmers want conserved because of its good litter size (8–10), and can thus help them increase income at a faster rate (Abigaba et al. 2022). Like most local pig breeds in Africa, there is little or no information on the phenotypic and molecular characterization of the Lusitu and Nsenga pig breeds of Zambia, an urgent research priority that should be considered by stakeholders.

8.4.6.5 Landim Pig

The Landim is an indigenous pig of Mozambique. In Mozambique, livestock plays an important role in the agriculture sector, due to its contribution to socioeconomic development and poverty reduction. Given the variations in climate, soil fertility, rainfall pattern, and altitude among the different areas, the country is divided into ten agroecological regions, each one with its own characteristic production systems and livestock breeds. Livestock is mostly composed of indigenous breeds: Landim cattle, goats, pigs, and

chicken, Angoni and Bovino de Tete cattle breeds, and Pafuri goat. Most native breeds are named as Landim, which in the South of Mozambique means indigenous or local (Cumbula and Taela 2020). The Landim pig is a small black pig kept by smallholder pig producers with 2–10 pigs per family on average (Chilundo et al. 2017). Unfortunately, little or no phenotypic and molecular characterization has been carried out on the Landim pig, and this needs to be urgently addressed by stakeholders to generate important data for its sustainable use and conservation.

8.4.6.6 Indigenous Pig Breeds of Angola

The *Porco do Bengo*, *Porco do Kunene,* and *Jambona Munhanda* are the main indigenous pig breeds of Angola. Traditional management practices include feeding pigs with scraps and crop residues. In peri-urban and rural areas, pigs forage on rubbish dumps. Pigs are a crucial source of meat and income in Angola. Like most local pig breeds in Africa, the *Jambona Munhanda* has social and cultural importance, while the other breeds have economic importance. Unfortunately, little research on the phenotypic and molecular characterization of the indigenous pig breeds of Angola has been carried out, and this needs to be addressed by stakeholders to provide valuable information for their sustainable use and conservation (Osei-Amponsah et al. 2017). The exotic breeds introduced and farmed in intensive systems include Large White, Landrace, and Duroc, which have continually been imported over the last years (Porter et al. 2016).

8.4.7 Exotic Pig Breeds and Pig Production in Africa

The major commercial exotic pig breeds that have influenced African Animal Agriculture over the years include the Large White, Landrace, Duroc, Hampshire, and Pietrain (FAO 2007a, 2015; Weka et al. 2020; AUIBAR 2019; Goraga et al. 2017). Although the use of these exotic breeds of pigs is popular in all regions of Africa (Table 8.1) on account of their relatively high production, they require more investments in housing, feeding, and health care. Consequently, most exotic breeds are found in medium-high production commercial systems where farmers invest in feed provision and health care. At the same time, local farmers are increasing crossbreeding their local stocks with these exotic genetics. Often, the crossbreeding is indiscriminate, leading to the dilution of adaptive characteristics in the crossbreds and often low production performance due to poor feeding and veterinary care. There is a need for improved capacity building for stakeholders, particularly pig farmers, to enable them to benefit from the improved genetics. Rwanda's modern pig husbandry practices usually involve imported exotic breeds kept in confinement and fed with concentrate feed, provided with clean water, vaccines, and other important inputs. Over 70% of pig enterprises in Rwanda are rearing exotic breeds, and the most popular pig breeds are Large White, Landrace, Pietrain, and Duroc, followed by indigenous and some crossbreeds between these exotic and indigenous ones (Kruger 2015). Hirwa et al. (2022) reported that 41 percent (41%) of households kept crossbred pigs, local (19.7%), Landrace (18.7%), Large White (12.1%), Pietrain (8.1%), and other breeds (0.3%). In most African countries, pig producers decide to breed any type of breed according to their availability, but also for production purposes. Commercial farmers mainly use improved breeds, while traditional farmers solely rely on the indigenous or crossbreeds. However, like in other countries, the lack of breeding centers (seed stock nucleus) poses a serious problem, since the majority of pigs in the country are highly inbred (Shapiro et al. 2017).

In the following sections, we provide summaries of the key features of the most popular exotic pig breeds in Africa.

8.4.7.1 Duroc

The Duroc pig breed (Fig. 8.12) originated from the eastern United States, and the foundation stock was originally called the Duroc-Jersey because of the red hogs that went into their foundation. One source of the red or reddish-brown

hogs found in the United States was reputed to be those that came from the Guinea coast of Africa. Durocs have considerable variation in color, ranging from a very light golden, almost yellow color, to a very dark red that approaches mahogany. The red is a very practical color that suits pork producers, and since it is a solid color, there is no concern about fancy points of proper markings. Durocs also have a medium length and a slight dish of the face with drooping. Indeed, Durocs constitute an important component of commercial semi-intensive and intensive pig management systems in many African countries on account of their superior growth, reproductive, and relatively good carcass traits (AUIBAR 2019; FAO 2015; Lichaba 2022). In the Republic of Congo, an average litter size per sow of 9 ± 0.8 head, a litter weight per sow of 25 ± 8 kg, and a breeding age of 8.3 ± 0.7 months have been recorded (Ognika et al. 2021). The average live weight of piglets is 1.32 ± 0.4 kg at birth, with average daily gains ADGs of 230 ± 0.5 g in the 2nd week, 370 ± 0.3 g in the 4th week, and 650 ± 0.8 g in the 16th week, respectively (Ognika et al. 2021).

8.4.7.2 Large White

The Large White was one of the original founder breeds of the British Pig Association, and the first herd book was published in 1884. The Large White got to South Africa in the 1890s and, as shown in Fig. 8.13, they are distinguished by their erect ears and slightly dished faces. They are long-bodied with excellent hams and fine white hair, and, as their name suggests, they are characterized by large size. Large Whites are valued for their bacon production.

The Large White has proved itself as a rugged and hardy breed that can withstand variations in climate and other environmental factors. Their ability to cross with and improve other breeds has given them a leading role in commercial pig production systems and breeding pyramids in many African countries (Aryee et al. 2019; Adjei et al. 2015b; Chimonyo and Dzama 2007; Lichaba 2022; Kanengoni et al. 2015). They and their descendants, the Yorkshire, are to be found in practically all crossbreeding and rotational breeding programs using two or more breeds. Modern breeding programs have developed separate sire and dam lines to produce purebred Large White terminal sires that excel in growth rate and lean meat percentage and are incorporated in most terminal sire breeding programs. In many African countries, including South Africa, Ghana, Kenya, Rwanda, and Nigeria, improved production performance has been obtained using the Large White in intensive management systems or crossing the breed with local sows (AUIBAR 2019; Osei-Amponsah et al. 2017; Kanengoni et al. 2015; Dube et al. 2012; Mbuthia et al. 2015). However, studies on blood antibody titers, protein, and globulin levels indicate that the Nigerian local breed, for instance, is superior to crosses

Fig. 8.12 The Duroc pig breed. (Credit: Prof. R. Osei-Amponsah)

Fig. 8.13 The Large White pig breed. (Credit: Prof. R. Osei-Amponsah)

between the Large White and Landrace (Abonyi et al. 2018). In the semi-intensive system, farmers in Kenya mainly kept Large White and Landrace and their crossbreeds on account of their faster growth rates and high mature weights. Additionally, the Large White in particular was preferred as the sire line in most commercial pig production enterprises due to high prolificacy and mothering ability (Mbuthia et al. 2015).

8.4.7.3 Pietrain

The Pietrain pig breed's birthplace is Pietrain, a village in Belgium. The breed is of medium size and is white with black spots. Around the black spots, there are characteristic rings of light pigmentation that carry white hair and erect ears. The Pietrain (Fig. 8.14) is very popular as a terminal sire in two of Europe's largest pig-producing countries, Germany and Spain. The Pietrain is renowned for its very high yield of lean meat, but this is often associated with the presence of the halothane gene for Porcine Stress Syndrome. For this reason, the use of purebred Pietrain in British pig production is relatively rare, and it is most commonly found in crossbred and synthetic terminal sire lines (https://www.thepigsite.com). Like the Large White, Landrace, Duroc, and Hampshire, the Pietrain is a major commercial exotic pig breed that has, over the years, been used in various pig improvement programs in Africa with varying degrees of success (FAO 2007a, 2015; Weka et al. 2020; AUIBAR 2019; Goraga et al. 2017; Hirwa et al. 2022).

8.4.7.4 Hampshire

The Hampshire pig breed (Fig. 8.15) was developed in the United States of America and is now one of the world's most important breeds. At a meeting of American breeders in 1890, the breed was renamed the "Hampshire," as the original pigs were imported from a farm in Hampshire, Wessex, UK. A breed society was established at the same time, and herd book recording can be traced for more than 100 years. The Hampshire is used extensively as the sire of crossbred pigs for the pork and manufacturing markets in many countries. It has the reputation of being the leanest of the North American Breeds, and most carcass competitions in North America are won by Hampshires and Hampshire crosses. In Africa, Hampshire has been popular in semi-intensive and intensive pig production systems on account of their lean carcasses, docility, and good mothering ability of its sows (AUIBAR 2019). Although often criticized for their large size, Hampshires are admired for their prolificacy, hardy vigor, foraging ability, and outstanding carcass qualities (http://afs.okstate.edu/breeds/swine/hampshire/index.html).

8.4.7.5 Landrace

Landraces have white skin, free from black hair, are lop-eared pigs (Fig. 8.16) with a long middle, light forequarters, and excellent ham development. The major faults with the original Landrace were leg weakness, splay legs, and nervous disorders such as porcine stress syndrome (PSS), which still occur in some strains. Landraces are

fast-growing and have a high percentage of carcass weight in the ham and loins. The sows are prolific breeders that farrow large pigs and like the Large White and the Duroc, have been used in many semi-intensive and intensive pig production systems in Africa (AUIBAR 2019). While this has helped improve the growth and reproductive performance of crossbred pigs, this poses a threat in terms of dilution of the adaptive traits of indigenous pigs (Osei-Amponsah et al. 2017, 2021). A comparative analysis of growth and reproduction performance between the Landrace, Large White, and local pigs in Uganda (Greve 2015) indicated an average litter size of 12, 11, and 8, respectively. The weaning to service interval (days) was also significantly better for the Landrace (38.3) and the Large White (47.1) compared to the local genotype (Greve 2015). In terms of pre-weaning mortality, however, the local breed was significantly ($p \leq 0.05$) superior, averaging 1.2 compared to 1.8 and 1.7 of the Landrace and the Large White (Greve 2015).

8.5 Sustainable Use and Conservation of Pigs in Africa

8.5.1 Pig Production Systems in Africa

Pigs are raised in a variety of production systems in Africa. The pig production systems are usually classified based on herd size, level of inputs in the form of housing, feeding, veterinary services, and purpose of production (Adjei et al. 2015b;

Montsho and Moreki 2012). The main pig production systems include the extensive/free-range, semi-intensive, and intensive systems (see Chap. 2). In most countries, the extensive traditional pig rearing system is the most predominant, mostly involving local breeds kept in the backyard and fed on kitchen waste and agricultural byproducts.

8.5.1.1 Extensive/Free-Range/ Scavenging System

The free-range scavenging system is a low-input–low-output production system. This means that there is little or no investment in housing, nutrition, and healthcare (Fig. 8.17) (Adjei et al. 2015b). The indigenous African breeds dominate in this system since they can survive and reproduce under low-quality feed and limited healthcare conditions. In this system, pigs freely roam around the homesteads, surrounding areas, and in garbage dump sites (FAO et al. 2017), scavenging and hunting for their own feed. For instance, most pig farmers in Cameroon (75%) are engaged in the traditional system of production, where mostly the local breeds of pigs (Bakweri, Bamileke, Mankon Long Nose, hybrids (local and exotic)) are reared with limited input (Ebwanga et al. 2021). The animals are left to fend for themselves and can be seen roaming the villages (Ebwanga et al. 2021; Pondja et al. 2015). Like many African countries, pig production in most areas of Ghana, Nigeria, Uganda, Tanzania, and Mozambique are dominated by traditional production systems and practices, characterized by small herds, low level of biosecurity and productivity, low market off-takes, and poor food safety, which pose substantial limitations on the public health and economic viability of smallholder farmers and public (Adjei et al. 2015b; Pondja et al. 2015; Kimbi et al. 2015). A study to characterize pig production systems in Ghana reported that free range and semi-intensive systems of producing local pigs were common, possibly due to the fact that the majority of the farmers who kept local pigs were involved in crop cultivation or fishing (Adjei et al. 2015b). Predominantly, local pig farmers practiced extensive/scavenging (56%) with very few practicing an intensive system of production (19%) (Adjei et al. 2015b). In most countries, during the crop growing seasons, pigs are tethered to protect the crops. Herd sizes range from two to ten sows. At night, pigs are housed in enclosures surrounded by a fence of sticks or in simple grass-thatched roof houses to provide shelter and protection from cold, rain, and predators (Fig. 8.17). The scavenged feeding materials are usually characterized by high fiber content and low nutritive value. Sometimes, kitchen refuse or crop byproducts such as rice or maize bran, banana or cassava peels, cooked pumpkins, etc., are offered to the pigs as supplements. The inadequate nutrition, coupled with poor healthcare and the low genetic potential of the indigenous breeds, are the reasons for their low productivity. In most cases, the pigs are not kept for meat for the household or as a regular source of cash income, but as an inflation-proof savings account or insurance policy. This entails that pigs are only sold when there is an emergency requiring some cash or when extra cash is needed to meet some household needs, such as the purchase of seeds or fertilizer and food during lean periods, payment of school fees and medical bills, and cash needs during festive seasons or funeral emergencies (Kaumbata 2012). Even though local pigs are reared under low-input systems, they have demonstrated resilience in adapting to low-input systems and have been instrumental in contributing to the improved livelihoods of millions of resource-poor farmers in rural areas. This presents an opportunity to exploit this adaptive potential by implementing genetic and nutrition improvement programs to enhance their productivity.

8.5.1.2 Small-Scale Semi-intensive System

This system is characterized by investment in improved husbandry practices such as construction of standard pig houses, healthcare, improved feeding, and acquisition of improved breeds (Fig. 8.18). Herd sizes are usually more than 5 sows but not up to 25 sows (Sharma et al. 1999), and in most cases, exotic boars are used in crossbreeding to take advantage of hybrid vigor. Pigs

Fig. 8.17 Extensive pig production practices showing poor housing (**a** and **b**), feeding/watering (**c**), and feed resources

may be released occasionally for grazing, but most of the time they are kept in enclosures. As in a study reported from the Democratic Republic of Congo, the pigs are mainly fed locally available feedstuffs such as maize/rice bran, green vegetables, kitchen leftovers, molasses, institutional/industrial byproducts, and often supplemented with commercial feeds (Akilimali et al. 2017). In Rwanda, the majority of pig producers are smallholder farmers who rear pigs in their backyards and house them in semi-permanent structures. Semi-intensive production system is also practiced in the country, where improved breeds are kept, and some commercial pig production management principles are applied. In Cameroon, about 20% of pig farmers practice the semi-intensive system of production, often in small family setups, where pens are constructed behind homes and on rented land (Ebwanga et al. 2021).

8.5.1.3 Medium- and Large-Scale Intensive Production System

These systems aim to produce meat for the market efficiently and profitably, usually with larger numbers of pigs. There is significant investment in the form of housing, feeding, healthcare, and marketing. Herd sizes are relatively large, 25–75 sows (Sharma et al. 1999) or more, and mostly exotic breeds are used. Breeding stock is usually imported or acquired locally from reputable sources such as research, training and religious institutions, and registered breeders. The pigs are kept in concrete-floored houses partitioned to accommodate different pig classes separately. The pigs are fed commercial feeds throughout the production cycle. Biosecurity measures are strictly observed to prevent disease and parasite outbreaks. In most cases, producers are certain about the market or where to sell the pigs. Meat processors may sign contracts with the pig producers to supply pigs of specific attributes at regular intervals. In Liberia, pig farming is a predominantly commercial activity with over 75% of farmers in commercial production systems, with peasant farming comprising about 20% and breeding and multiplication making up only 4% (Karnuah et al. 2018). Pigs in Liberia are mostly kept in housing, with 71% of pig farmers providing permanent structures and 24% providing

Fig. 8.18 A farmer feeding pigs in a small-scale semi-intensive production system. (Credit: Prof. R. Osei-Amponsah)

sheds. Only 5% of pig farmers provided no housing for their stock. The main reason for the high level of housing provision is the fact that most farmers are keeping exotic breeds such as the Landrace, Large White, and Hampshire in intensive systems. As expected, therefore, most pigs in Liberia are continuously confined (82%), with a little over a tenth of pig farmers (11%) never confining their animals (Karnuah et al. 2018).

8.5.2 Pig Improvement Programs

Pig production is a growing animal resource sector with the potential to contribute to protein food security, wealth creation. and sociocultural values while contributing to sustainable use and conservation of the available *Sus* resources. Reports on the existence of organized indigenous pig conservation and improvement breeding programs in African countries are lacking. As earlier described, the indigenous pigs are commonly kept under free-range scavenging production systems. The proliferation of exotic breeds in many African countries led to unplanned crossbreeding, particularly in semi-intensive production systems, to improve the productivity of the indigenous pig breeds. The crossbred pigs usually find their way into the free-range production system, where uncontrolled mating is rampant. This poses a serious threat to the indigenous pig genetic resources, which possess valuable adaptive characteristics suitable for low-input systems. Despite the absence of systematic within-breed genetic improvement programs for indigenous pig breeds and the prevalence of unplanned crossbreeding, there is high potential for success for such programs because superior genes can be spotted in a few animals within the African indigenous pig breeds.

The exotic pig breeds in Africa represent a valuable genetic resource that is significantly contributing to the development of the pig industry in many African countries. For the exotic pig genetic resources to benefit smallholder farmers in rural areas, careful and proper breeding strategies and designs are needed. The within-breed genetic improvement program for local pigs at the community level, coupled with systematic and controlled crossbreeding, can be a powerful tool to improve pig productivity on smallholder farms. The prolificacy and fast-growing nature of pigs and the adaptive characteristics of indigenous breeds are potent factors that have not been exploited yet to the benefit of smallholder farmers. Such programs can represent the best in situ conservation strategies for indigenous genetic resources that are currently contributing to food production (FAO 2007a). In situ conservation allows the animals to keep adapting to changes in their environment while performing other important roles, such as ecosystem services. Sustainable conservation, improvement, and utilization of the African indigenous pig genetic resources require a thorough characterization of the attributes and possible uses for the breeds and the development

of niche markets for their products. Utilization of indigenous pig genotypes in communal areas has the potential to increase food security, reduce poverty, and improve the livelihoods of resource-poor farmers (Halimani et al. 2020). The Convention on Biological Diversity (CBD) defines sustainable use as the use of components of biological diversity in a way and at a rate that does not lead to the long-term decline in biological diversity, thereby maintaining its potential to meet the needs and aspirations of present and future generations. In designing community-based breeding programs, breeding goals of smallholders, which are often multifaceted compared to the commercial pig farmers who focus on a few traits of economic importance, such as fast growth rates, larger carcasses, and disease tolerance, should be considered. Goals for smallholders include: color pattern, temperament, mothering ability, foraging behavior, adaptability, and the ability to survive and reproduce in low-input systems (Halimani et al. 2020). There is also a need to incorporate indigenous knowledge in the breeding programs. Several possible schemes have been proposed, including sire rotation or loan schemes, nucleus-based programs run by the public sector and linked to community-level multipliers, and other community-based programs where selection is done at the community level. There is an opportunity to use recent advances in technology, especially assisted reproductive technologies and genomics, to quicken the process without a loss of diversity. Possible interventions suggested to achieve sustainable conservation and utilization of pig genetic resources in Africa (Halimani et al. 2010, 2020) are summarized in Table 8.2.

8.5.3 Conservation of African Pig Genetic Resources

Detailed information on the significance of conservation of Africa's AnGR in the context of the GPA on AnGR, including past and current initiatives as well as emerging technologies and the role of stakeholders, has been presented in Chap. 25. In this section, we throw more light on specific conservation interventions, challenges, and opportunities in the conservation of pigs. In Africa, the numbers, breeds, population genetic structures, attributes, and risk status of local pig genetic resources are understudied. Available research findings indicate that local pigs are tolerant to parasites that are endemic in their production environment. They also have a better chance of surviving various disease outbreaks and have a higher capacity to utilize fibrous and poor-quality feed resources compared to exotic breeds (Halimani et al. 2010). Sustainable use and conservation of pig genetic resources is the surest way to ensure that they remain functional parts of the prevailing systems and play their useful roles of contributing to protein food security, supporting livelihoods, and providing employment to many in Africa. Smallholder farmers in Africa have, for millennia, played key roles in conserving and using native breeds to support their livelihoods. They have maintained the rich biodiversity and the associated local knowledge, in addition to the crucial role in sustaining livelihoods and other environmental benefits. Future conservation interventions should, therefore, aim to support these efforts in order to maintain the existing genetic wealth (AUIBAR 2019).

Two main methods are available for conserving AnGR in Africa, namely in vivo conservation of animals (which includes in situ and ex situ) and in vitro conservation of germplasm material (see Chap. 25). In terms of in situ conservation, smallholder farmers in Africa have, for millennia, played key roles in conserving and using native breeds to support their livelihoods. They have maintained the rich biodiversity and the associated local knowledge in addition to the crucial role in sustaining livelihoods and other environmental benefits (AUIBAR 2019). However, conserving their pig genetic resources solely in situ places them at a huge risk from artificial and natural disasters. African countries should therefore improve their human and institutional capacity to take advantage of ex situ technologies, including ex situ in vivo or cryopreservation. Already, the AU-IBAR and its stakeholders have established regional gene banks in Africa to provide a backup facility where countries can cryo-

Table 8.2 Key outputs, activities, and actors for sustainable utilization and conservation of pig genetic resources in Africa

Variable	Expected outputs	Activities	Responsibility
Food and nutrition	Number of pig farmers increased	Conduct a needs assessment study, followed by various awareness campaigns. Facilitate information dissemination among farmers and between farmers and extension through [a]ICTs	Researchers, extension, government, farmers, [b]NGOs
	Reproductive efficiency enhanced and mortality rates reduced	Improve animal health and housing management. Implement farmer capacity-building programs	Researchers, extension, government, farmers, NGOs
	Environmental and public health improved	Strengthen veterinary services. Establishing biosecurity structures to control zoonotic diseases Improve product quality and quantity, and timing, as well as addressing price and policy issues	Researchers, extension, government, farmers, NGOs
Income generation	Lucrative pig market identified	Conduct qualitative and quantitative value chain analysis. Create niche markets. Establish processing facilities	Researchers, extension, government, farmers, NGO
	Pig producer cooperatives established	Incentive group farming and contract farming. Facilitate credit support for the farmer groups in production. Create small farmer abattoirs	Researchers, extension, government, farmers, NGOs

preserve their unique porcine germplasm (AUIBAR 2019). As a result of the predominant free-range/extensive production systems in Africa, understanding the effects of admixture on important adaptive and economic traits of local pig breeds will be critical for developing sustainable conservation programs to prevent the decline of these genetic resources (Osei-Amponsah et al. 2017). Data on phenotypic characteristics and production systems of pigs are essential in developing breeding, management, and conservation programs, but these remain unavailable in most countries of Africa (Karnuah et al. 2018).

As signatories to the Global Plan of Action (GPA) on Animal Genetic Resources (FAO 2007b), African countries have committed to developing national conservation policies, establishing or strengthening in situ and ex situ conservation programs, developing and implementing regional and global long-term conservation strategies, and developing approaches and technical standards for conservation. Although the commonest conservation methods to date have been the continuous keeping of animals in their natural environments (in situ conservation), events over the last four decades indicate clearly that Africa needs to embrace and use other forms of conservation of its animals. For instance, there have been many natural and man-made disasters that have wiped out entire herds, leading to the need for total restocking. Additionally, the negative effects of climate change on animal production, disease emergence, epidemics and pandemics, increasing demand for animal protein, and other uncertainties indicate the risk faced by Africa's animal genetic resources. In view of these, other means of conservation, including keeping animals on government farms, research station farms, or national parks (ex situ in vivo conservation), and cryopreservation (ex situ in vitro conservation) should be embraced. The reasons for conserving local pig genetic resources vary from current utility to the ability to meet future challenges in a dynamic environment. Unfortunately, there is a big policy gap in most African countries with regard to the conservation of AnGR in general, and it is imperative that policymakers be made aware of the value of AnGR. The costs of conservation can be met by increasing the market value of neglected breeds so that they eventually become self-sustaining (Halimani et al. 2010).

8.6 The Economics of Pig Production in Africa

In many African countries, pigs and pig products are marketed through formal and informal marketing channels. The indigenous and the crossbred pigs from the free-range/scavenging and semi-intensive systems are usually marketed through informal channels, while the pigs from medium and large-scale intensive pig farms are marketed through formal marketing channels. The free-range/scavenging and semi-intensive systems usually supply the local consumers in peri-urban and rural areas through a simple marketing channel presented in Fig. 8.19. The marketing channels are dominated by male intermediaries who collect and assemble pigs from producers' homesteads and rural markets at low prices. The pigs are then resold to butchers at high market margins. The animals are then slaughtered, and the meat is supplied to meat kiosks, restaurants, bars, and pork joints. The challenges associated with the informal marketing channels and the possible interventions are detailed under Sect. 8.7.3.

The medium- and large-scale intensive pig farms usually supply consumers in big cities and urban areas. The market system is well developed ann organized and requires a regular supply of large numbers of pigs with specific attributes. Producers are certain about market availability, and production is sometimes based on contract farming, which specifies the number of pigs required at specific intervals. Pricing is based on the cost of production and the desired level of profits; hence, producers are the price makers. Figure 8.20 shows the simplified marketing channel for pigs from medium- and large-scale intensive pig farms.

8.7 Challenges of African Pig Production

African pig farmers, especially smallholder farmers in peri-urban and rural areas, face many technical and management problems that limit the development of the pig industry in Africa. For instance, farmers in both subsistence and commercial pig production systems in Southern Africa indicated diseases and parasites, followed by feed shortages, inbreeding, and abortions as major constraints for pig production (Madzimure et al. 2013). Additionally, like the case of Botswana, several challenges face commercial pig operations in Africa, including high feed costs, inadequate slaughtering facilities, unorganized marketing, poor breeding stock, transboundary diseases, and inadequate extension service (Montsho and Moreki 2012; Shyaka et al. 2022). A major constraint in conserving pig genetic resources in Southern Africa is the lack of market participation of the majority of pig farmers, who keep small herds mainly for subsistence. The major barriers to market participation are production constraints, information asymmetry, underdeveloped markets and support infrastructure, limited finance and other resources, and inadequate knowledge (Halimani et al. 2020). These challenges have significant negative impacts, ranging from poor productivity to the entry of unsafe products in the pig value chain, which poses serious health risks to consumers. The challenges can be grouped as follows:

(i) Prevalence of parasites, diseases, and poor disease control measures
(ii) Poor pig nutrition, high feed costs, and feed availability
(iii) Unavailability of systematic breeding programs and indiscriminate crossbreeding
(iv) Unorganized and low-value marketing system
(v) Erratic meat inspection and inadequate hygiene slaughter facilities
(vi) Inadequate extension and veterinary services

Overcoming the challenges requires concerted and coordinated efforts by various stakeholders and players in the pig value chains (Gebrehawariat et al. 2017; Shyaka et al. 2022; Ibeagha-Awemu et al. 2019).

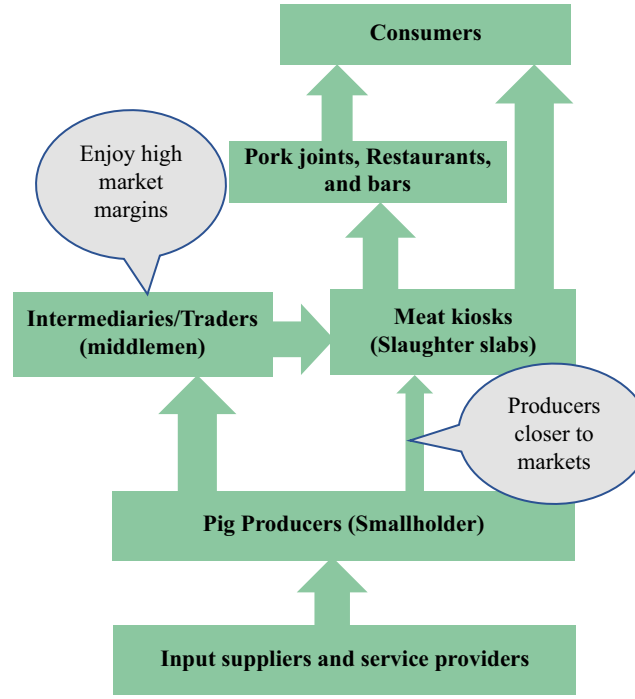

Fig. 8.19 Simplified marketing channel for indigenous pigs from the free-range/scavenging and smallholder semi-intensive systems

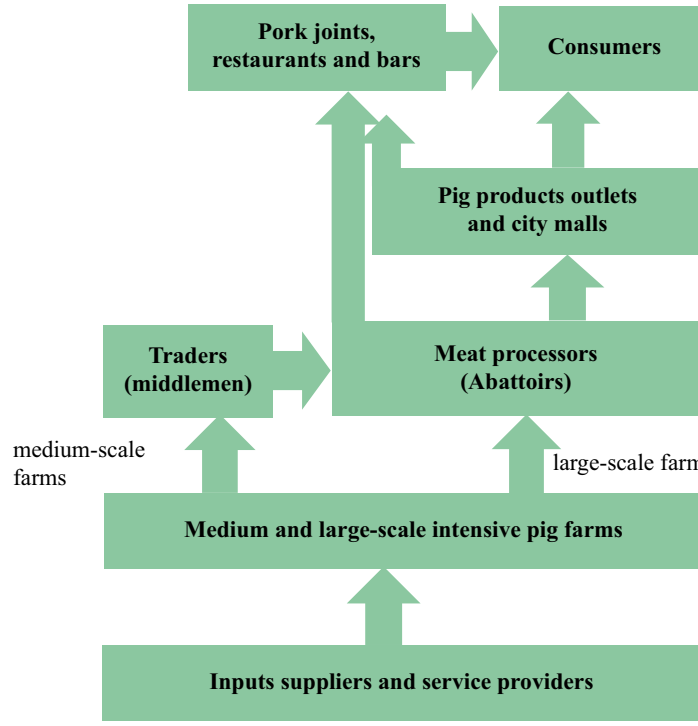

Fig. 8.20 Simplified marketing channel for pigs from medium and large-scale intensive farms

8.7.1 Prevalence of Parasites and Diseases and Poor Disease Control Measures

Disease and parasite infestation is a big challenge for pig production in many African countries. The most prevalent and endemic disease is African swine fever (ASF), a viral disease that spreads rapidly and is associated with high morbidity and mortality (Ebwanga et al. 2021). Other prevalent infectious diseases include swine erysipelas, brucellosis, exudative dermatitis (greasy pig), respiratory diseases, swine dysentery, mastitis, and porcine parvovirus (Weka et al. 2020; Dione et al. 2017). African Swine Fever is a deadly disease affecting the pig industry in Africa. Unlike most livestock diseases, to date, vaccine development to help control ASF remains elusive. Attempts aimed at preventing and controlling ASF have been complex, expensive, and unsuccessful and will require more innovative strategies (FAO et al. 2017) and funding. Additionally, parasitic diseases such as Helminthosis (Strongylid parasites, *Strongyloides ransomi, Ascaris suum*, *Metastrongylus* sp., *Trichuris suis, Taenia solium*), protozoa (coccidiosis and trypanosomiasis), and ectoparasitism also erodes the economic gains due to reduced weight gain and litter size, poor growth rates, condemnation of carcass at slaughter, and sometimes death (Weka et al. 2020).

Disease control measures in most smallholder pig farms in Africa are generally poor (Dione et al. 2017). Vaccination is a major focus of disease prevention and herd-health management in pig production. Biosecurity measures are absent in most pig farms, and insufficient confinement/quarantine of newly introduced breeding stock, leading to disease introduction and circulation from one farm to another farm (Shyaka et al. 2022). The free-range production system predominant in most peri-urban and rural areas of Africa makes it almost impossible to bring disease outbreaks and parasite infestation under control. Additionally, public and private veterinary services, as well as pig farmers, lack funding and compensation and insurance policies, making investment in commercial pig enterprises riskier and increasingly unattractive. High cost of veterinary drugs and services, and proliferation of fake, expired, and ineffective drugs frustrate disease and parasite control efforts (FAO et al. 2017; Tatwangire 2014).

8.7.2 Poor Pig Nutrition and High Feed Costs

Pig feeding in Africa is usually dictated by the prevalent production system, and challenges related to pig feeding also differ by the production system practiced. The free-range scavenging system is a low-input–low-output production system (Adjei et al. 2015b). This means that there is little or no investment in housing, nutrition, and healthcare. Pigs roam around the homesteads in search of feed. Feed availability and optimal nutritive value of the feedstuffs are seasonal. The scavenging feed resources are abundant during the rainy season and at harvest, and the nutritive value is optimal during the same periods. In the dry season, feed becomes scarce and is usually characterized by high fiber content and low nutritive value. Sometimes the pigs are supplemented with crop byproducts (cooked pumpkins, rice/maize bran, etc.), kitchen waste, and leftover human food. In the smallholder semi-intensive and medium and large-scale intensive pig farms, pigs are fed with commercial feeds. Due to the rising costs of feed ingredients, the commercial feeds are increasingly becoming expensive (Madzimure et al. 2013, 2014). These high prices are due to a lack of raw materials and feed ingredients on local markets, as corn, for example, is used for human food, and expensive imported feed ingredients. Although the establishment of local feed mills has been promoted as a strategy to improve the availability of animal feed, there is a need for research and development of alternative, cheap, and innovative sources of animal protein feeds, such as insects (Shyaka et al. 2022). Some farmers are now practicing what is known as the blended feeding approach, especially in smallholder semi-intensive systems, where, in addition to the commercial feeds, animals are also supplemented with locally available feedstuffs such as vegetables, crop byproducts, kitchen/institutional food remains, and industrial

byproducts. This feeding approach has resulted in significant reductions in feed costs and increased profitability of pig enterprises.

8.7.3 Unorganized and Low-Value Marketing System for Smallholder Rural Farmers

Pig market structure in Africa varies according to country, region, and production system. Markets for indigenous pigs from low-input systems are mostly informal and exploitative. In many areas, farmers are not organized into formal organizations, road infrastructures are poor, and access to essential services (such as veterinary, credit/loans, etc.) is a challenge. This puts them into a weak negotiation position, increases the transaction costs, and reduces their competitiveness when dealing with supply chains that are becoming formalized and upgraded.

The informal market structure is usually dominated by pig brokers and traders (intermediaries/middlemen) who assemble live animals from farmers' homesteads and local markets. At these selling points, the pigs are sold based on physical appraisals of size, body conformation, and health status, and not on a live weight basis. The prices are usually arrived at based on how skillful the buyer is in price negotiation and how desperate the farmer is for money, to meet the need at hand. The brokers are highly knowledgeable about pig price trends and act as key persons connecting rural producers to different slaughter slabs/houses and other higher-level traders (Shyaka et al. 2022). In Rwanda, for instance, live pig markets constitute a major avenue for stakeholders to buy and sell pigs. Middlemen or brokers play a key role in this pig trade: setting animal prices, examining pigs to ensure that they are free of disease, helping supply pigs to various abattoirs and for export (Shyaka et al. 2022). For instance, lingual palpation helps identify cysticercosis infection, with affected pigs sold at reduced prices. Some of the risks identified, among others, include a lack of biosecurity and unsanitary conditions, particularly at abattoirs (Shyaka et al. 2022).

A major constraint in conserving pig genetic resources in southern Africa has been reported as the lack of market participation of most pig farmers who keep small herds mainly for subsistence, due mainly to production constraints, information irregularity, underdeveloped markets and support infrastructure, limited finance, and inadequate knowledge (Halimani et al. 2020). Pig farmers, especially in rural Africa, are poorly organized and therefore unable to utilize the advantages of collective marketing and high bargaining power. This limits farmers' efforts to upgrade into various pig-related market exchanges at different nodes of the value chain, creates inefficiencies, and opens doors for exploitation and poor-quality products (Tatwangire 2014). Absence of market information puts the producers at a disadvantaged position, which turns them to be price takers instead of price makers. Formal pig markets exist but require a regular supply of a large number of pigs with specific attributes. These are usually accessed by farmers in intensive and semi-intensive systems because the herd sizes in these systems are relatively large and uniform, hence can meet a regular supply of pigs. Therefore, there is a need to empower and build the capacity of smallholder rural pig producers so that they become active participants in the pig value chain. This can be done through capacity building and the establishment and operationalization of community-based pig producer cooperatives. Functional pig producer cooperatives are instrumental in consolidating smallholders' bargaining power, increasing access and management of lucrative markets, enjoying the benefits of economies of scale, enhancing access to credits/loans and livestock extension services, and having a voice on issues that affect their well-being.

8.7.4 Unavailability of Systematic Breeding Programs and Indiscriminate Crossbreeding

Past and ongoing pig breeding programs in Africa, the breeding companies involved, as well as molecular and assisted reproductive innova-

tions, are detailed out later in this book (refer to Sect. 19.6 of Chap. 19). Unlike the imported exotic breeds, most indigenous African pig breeds have no distinct and fixed characteristics that can qualify them to be classified into distinct breeds. The indigenous pig populations are dominated by crossbreds with no pedigree information for traceability. The free-range production system predominant in smallholder pig farms and the absence of record keeping make it difficult to trace the parentage and genetic composition of offspring. Small-scale intensive and large-scale commercial farms import breeding stock or obtain them from local breeders and institutions. Smallholder rural producers acquire breeding stock from neighbors/friends and sometimes from research, training, and religious institutions. Selection of breeding stock is often based on reproductive and growth performance, such as large litter size, conception rate, weaning to conception interval, mothering ability and growth rate, feed conversion efficiency, weaning, and slaughter weights, respectively. Inadequate and unreliable availability of breeding stock and absence of planned breeding schemes for smallholder pig farmers have resulted in high levels of inbreeding, thus leading to small litter sizes, poor growth rates, and small animals (Tatwangire 2014; Shyaka et al. 2022).

The uncontrolled exchanges and hazardous crossing between pig breeds constitute some risks of either the extinction of the indigenous breeds, or the problem of consanguinity, or even the threat of erosion of genetic diversity (Kiendrebeogo et al. 2012). There is a risk of losing the indigenous pig biodiversity because of the race to breed for high production capacity of pigs via crossing with imported exotic breeds. In some countries, indigenous breeds have been replaced with exotic breeds such as Large White, Landrace, Hampshire, and Duroc to help meet the demand of the market system (Weka et al. 2020). Indiscriminate crossbreeding of indigenous pigs with imported pigs should be discouraged because it dilutes the ability of indigenous pigs to resist disease challenges, hence threatening the genetic resource. In addition, indigenous pigs survive well under resource-limited, low-input systems. The conservation of indigenous pigs that will be bred and sold to rural farmers for sustainable rural development is recommended (Madzimure et al. 2013). Indiscriminate crossbreeding, replacement of indigenous pigs with imported pigs, and lack of clearly defined policies on conservation of indigenous genotypes threaten their continued existence (Halimani et al. 2020) and chance to contribute to the development of future breeds. Furthermore, the lack of the requisite human and institutional capacity for sustainable use, improvement, and conservation of pig genetic resources in Africa remains a major challenge and needs appropriate stakeholder intervention and support, as well articulated later on in Chaps. 27 and 28 of this book.

8.7.5 Erratic Meat Inspection and Inadequate Standard Slaughter Facilities

Livestock products, including pork and other pig products, pose a potential public health risk if poorly handled and processed. The supply of safe pork and other pig products relies on sound parasite and disease control programs and strictly regulated pig slaughter and carcass handling and processing systems. Reports show that there is poor and inadequate infrastructure development in many African countries to guarantee safe and hygienic handling of pork and other pig products (Shyaka et al. 2022). While formal pig abattoirs exist in many urban and peri-urban areas for the slaughter and processing of animals from medium and large commercial farms, the majority of pigs from the informal markets are slaughtered at informal slaughter facilities. Reports (FAO et al. 2017; Tatwangire 2014; Shyaka et al. 2022) on the prevalence and existence of informal, unregulated, and unhygienic pig slaughter slabs are not uncommon on the continent. In many areas, sufficient formal and regulated slaughterhouses are not available to handle the supply of pigs from smallholder rural farms.

Veterinary and public health officials in many African countries are entrusted and mandated with the responsibility of enforcing sanitary stan-

dards and regulations that improve the quality and safety of pork and other meat products. However, in many instances, meat inspection is rarely carried out in farms, and individuals practice backyard slaughter on market days and during festive seasons. Unfortunately, even at certified slaughter areas where routine veterinary inspections are carried out, poor and unhygienic conditions are prevalent. In terms of traceability, no records are kept on the source of animals, the number of animals slaughtered at a particular period, carcasses approved for consumption, organs, or carcasses condemned, as well as the final destination of slaughtered animals (Shyaka et al. 2022). Sometimes, there is a lack of clean water, dysfunctional refrigeration facilities, and unhygienic trucks transporting carcasses, leading to increased potential for contamination. Although abattoirs could be good locations for passive disease surveillance, the absence of records defeats this important function. The level of awareness among pig producers, processors, veterinarians, and public health officials on issues of pork safety is still low and a big concern for pork consumers. There is poor enforcement of regulations and safety standards even when relevant policies are clear; there is a lack of inspectors to conduct ante-mortem, visual inspection of meat organs and lymph nodes, and further testing of pork in the laboratories.

8.7.6 Poor Access to Livestock Extension, Veterinary, and Other Services

The problem of inadequate and often poor human and institutional capacity for sustainable use, production, breed improvement, and conservation of Africa's AnGR and the urgent need for stakeholder intervention have been highlighted in many sections of this book. Chapters 27 and 28 call for improvement in human and institutional capacity, including the provision and maintenance of appropriate infrastructure (see Sects. 27.7 and 28.2.4). For instance, livestock extension and veterinary services are instrumental for enhancing pig husbandry practices and market access. Producers need relevant and timely information on feeding, breeding, healthcare management, and market availability, as well as access to inputs. Unfortunately, in most regions of Africa, personnel to provide such services to pig farmers are usually inadequate or are not available in many areas. In many countries, qualified and experienced veterinarians are being replaced by less qualified and inexperienced para-veterinarians and community animal health workers. In other instances, public veterinarians have limited their services only to cattle production, leaving the other livestock production systems to para-veterinarians who, in most cases, are not effectively supervised (Shyaka et al. 2022). Other reports indicate the prevalence of high extension officer–farmer ratios, such as one officer to 2300 farmers, as opposed to the recommended ratio of 1 officer to 400 farmers (Benor et al. 1984). Hence, appropriate interventions are needed by governments and other relevant stakeholders to create enabling environments for the pig industry to grow and thrive. There is a need to enhance livestock extension and veterinary service delivery by making sure that the agriculture and public health sectors are adequately staffed with well-trained and skilled personnel to provide appropriate veterinary services in support of animal production. In addition to the provision of animal health services, extension officers are also a useful link between farmers and researchers and play critical roles in farmer capacity building through technical and leadership trainings and facilitation of farmer-to-farmer learning through exchange visits, on-farm demonstrations, field days, and agricultural/animal shows (Kaumbata et al. 2021).

Providing adequate access to formal financial services for smallholder pig farmers in most developing countries is a challenge because commercial banks do not consider them as viable clients, or the service centers are located very far away from their communities. In certain livestock improvement initiatives, the village saving and credit scheme (VSCS) has been included to help address this challenge (Kaumbata 2012). Such schemes will help pig farmers access credit at affordable interest rates. Others, including vet-

erinarians, community animal health workers, and pig assemblers and traders, can also benefit from such initiatives.

8.8 Opportunities for Sustainable Pig Production in Africa

Pig production offers wealth creation opportunities to actors on the pig value chain. Smallholder farmers benefit from quick returns for manure used in crop production. Several opportunities exist that, if well exploited and utilized, can enhance the growth of the pig industry in Africa. In the first place, demand for animal products, including pig products, in developing countries will continue to rise during the next three decades due to human population growth, urbanization, per capita income growth, and changing eating habits (Delgado 2005). The rising demand for animal products creates ready markets for pig products and direct income growth opportunities for pig producers, including smallholder rural farmers. In terms of consumer health concerns, meat quality and sensory properties have become important aspects of meat production and consumption in Africa (Hoffman et al. 2005). There is an urgent need for the pig industry to respond appropriately by improving acceptance of pork, particularly with reference to consumer demand for leaner pork.

Secondly, African indigenous pigs demonstrate resilience in surviving and reproducing under poor nutrition and healthcare management conditions. Indigenous pigs have, for millennia, proved to be instrumental in enhancing the livelihoods of many rural farmers because of their ability to survive and reproduce under conditions of poor nutrition, housing, disease, and parasite control. Despite demonstrating these important adaptive traits, the indigenous pigs have been ignored because they are apparently regarded as less productive without subjecting them to appropriate improvement programs. These adaptive traits need a thorough study on how they can be improved and used for the benefit of the pig industry (Ibeagha-Awemu et al. 2019). At the same time, uncontrolled exchanges and hazardous crossing between breeds constitute some risks of either the extinction of the indigenous breeds, or the problem of consanguinity, or even the threat of erosion of genetic diversity. Genetic characterization of indigenous African pig breeds, for instance, should help develop more sustainable breeding programs, particularly in low-input breeding systems (Kiendrebeogo et al. 2012).

The community-based within-breed genetic improvement program for indigenous pigs, coupled with systematic and controlled crossbreeding, can be a powerful tool to exploit heterosis for adaptive, reproductive, and productive traits for the improvement of pig productivity in smallholder farms. Indigenous and crossbred pigs are known for their ability to convert low-quality feedstuffs into valuable outputs. This presents an opportunity to use abundant green forages, crop residues, kitchen and institutional remains of human food, and industrial byproducts for feeding the pigs for the production of valuable pig products. Finally, the availability of imported exotic pig genetic resources in many African countries entails that producers have breeds suitable for existing production systems. Hence, producers can use indigenous, exotic breeds, or their crossbreds depending on consumer preferences and available niche markets.

8.9 Implications and the Way Forward

The rich diversity of pig genetic resources in Africa, their unique adaptive traits, and socioeconomic, cultural, and economic values, as well as their roles in ensuring protein food security, cannot be overemphasized. Africa, however, needs to ensure the sustainable use and conservation of these valuable animal genetic resources by promoting the many opportunities they offer while addressing various challenges associated with various production systems (Ibeagha-Awemu et al. 2019). There is high potential for using indigenous pigs in subsistence-oriented production systems and for crossbreeding of indigenous

pigs with imported breeds in market-oriented systems (Madzimure et al. 2013).

Most importantly, all stakeholders along the pig value chain need to recognize their unique roles in achieving this noble objective and ensuring that pigs remain important components of the animal agriculture sector in Africa. Sustainable development of the pig sector in Africa hinges on active participation of all stakeholders working together to address constraints to pig production and marketing (Ibeagha-Awemu et al. 2019). Constraints in pig production call for integrated, sustainable, practical policies on health, genetics, feeds, and management practices, as well as the organization of producers. In order to meet the demand for proteins by the growing human population in Africa, pig production presents immense opportunities for stakeholders (FAO et al. 2017).

For a sustainable utilization of pig genetic resources, therefore, we need to:

(i) Improve on the capacity of pig farmers and producer organizations to be able to adopt emerging technologies in pig production and health.
(ii) Promote technical and managerial skills among all stakeholders.
(iii) Establish pig breeding centers for breeding pigs and artificial insemination, and train farmers, technicians, and extension agents in AI and on the importance of record keeping, and provide the infrastructure for implementation.
(iv) Improve the capacity of farmers for biosecurity and disease control.
(v) Encourage feeding formulation based using locally available feed resources and subsidized imported feed ingredients.
(vi) Utilize animal biotechnology in the characterization and genetic improvement of local pigs.
(vii) Add value to local pig genetic resources through niche markets to ensure their sustainable use and conservation.

Investments in research, development, and promotion of alternate feed sources, superior genetics, and veterinary services are also needed. Regular training and supply of information on biosecurity, as well as provision of needed resources, will help in disease prevention and control programs, including epizootic and zoonotic diseases. Investments are also needed to support value chain actors through the establishment of community-based producer cooperatives, strengthening market information, and construction of more standard slaughterhouses designed to ensure food safety and public health (Shyaka et al. 2022). All these actions require commitment from national governments in terms of appropriate policies and funding to assist pig farmers and other stakeholders to improve production. Additionally, effective regular education and cheap technologies that help improve biosecurity, especially for the small-scale free-ranging pigs, should be encouraged. There should be more incentives for investment in pig farming to help improve the livelihoods of smallholder farmers and consequently improve food security (FAO et al. 2017). Recognizing the challenges and the opportunities that exist in the pig sector, the AU-IBAR, the FAO, and the International Livestock Research Institute (ILRI) have been collaborating since March 2013 to develop an Africa-wide strategy for the prevention and control of African Swine Fever (ASF). To this effect, a Taskforce drawn from the three organizations was set up and has worked extensively on the strategy (FAO et al. 2017).

Sustainable management and conservation of Africa's pig genetic resources will no doubt contribute to achieving the 2030 Sustainable Development Goals (SDGs), particularly Goal 2, which aims to end hunger and ensure access by all people to safe, nutritious, and sufficient food all year round; and Goal 8, which promotes sustained, inclusive, and sustainable economic growth, full and productive employment, and decent work for all. In this chapter, we have highlighted the rich pig genetic resources available in Africa, including the role of stakeholders in the value chain, and made a case for their sustainable use and conservation. Most of the challenges confronting pig production in Africa also provide many opportunities for bringing on board the private sector and modern technologies for improved production and greater efficiency.

There is a need for African national governments to collaborate with the private sector to encourage investments in the pig industry while empowering farmers through their producer cooperatives to access credit and providing them with regular training on various aspects of pig production, including the use of appropriate technology. Governments need to invest in the characterization, inventory, and monitoring of local pig breeds while improving on human and institutional capacity to ensure their sustainable use and conservation. Moreover, stakeholders should invest in research to develop a vaccine for ASF, which has the potential to totally wipe out all pigs on the African continent. Until this objective is achieved, strict adherence to recommended biosecurity protocols, intensive and more controlled pig production, as well as vibrant national agricultural livestock extension services, should be encouraged. Finally, in situ and ex situ in vivo conservation of Africa's pig genetic resources should be considered a priority. An important route to ensure sustainable use and conservation of Africa's pig genetic resources is stakeholder awareness creation on the value of pigs and capacity building of players along the value chain to enable them to take advantage of existing and emerging technologies in their operations.

8.10 Conclusions

In this chapter, we have provided information on the rich pig genetic resources of Africa to motivate stakeholders to take appropriate actions for their sustainable use and conservation.

African indigenous pig breeds and their crosses that are well adapted in Africa are characterized by small body size (adult around 60 kg), relatively poor growth rate and performance, sturdy, small litter size, difficult husbandry conditions, and can survive on low-quality feed, including crop residues, household wastes, and grass. Clearly, a lot needs to be done in terms of phenotypic and molecular characterization of indigenous pig breeds of Africa to provide valuable information on their adaptive, production, carcass quality, and disease resistance profiles and make a case for their conservation. To ensure optimum production of indigenous pig breeds, it is important that stakeholders improve their feed resources using locally available products with higher protein and energy contents to allow for faster growth and improved carcass quality.

Due to an expected ever-growing demand for animal products in Africa, fueled by human population growth, urbanization, increased per capita incomes, and changing eating habits, many African countries are likely to see more large-scale investment in pig production. The number of smallholder pig producers in rural and peri-urban areas will also continue to increase. Growth in domestic and regional demand for pork is likely to remain higher than growth in pig production. Therefore, the business-as-usual scenario of pig production will not satisfy the local demand for pork and other pig products in the coming years, unless measures are taken to promote improvements in the pig value chains, particularly for the smallholder pig producers.

Pig production will continue to contribute to poverty reduction in various ways, including an increase in food supply, a source of income, and a means for capital accumulation, employment opportunities, and supply inputs and services for crop production. Pigs are also among the few animals able to convert the otherwise waste byproducts of agroindustry into quality animal protein for human consumers, and thus, pig production provides meat and will therefore remain an increasing income earner for smallholder livestock farmers in Africa. As a species, the pig's relatively short production cycle, high prolificacy, ability to survive on a wide range of feedstuffs, and high carcass yield will continue to make it valuable to African animal agriculture.

Challenges faced by smallholder pig producers have been highlighted in this chapter for immediate attention by stakeholders. At the same time, opportunities exist that, if well exploited and utilized, can enhance the rapid growth of the pig industry and overall development of animal agriculture in Africa. Finally, the need for concerted and coordinated efforts by all players in the pig value chain to capitalize on the existing opportunities to elicit growth, development, and

improvement of the valuable pig genetic resources of Africa for food security and improved livelihoods cannot be overemphasized.

9 African Dromedary Genetic Resources, Diversity and Breeding Systems

Semir B. S. Gaouar, Imane Meghelli, Zoubeyda Kaouadji, Félix Meutchieye, and Djalel E. Gherissi

Abstract

This chapter thoroughly investigates the multifaceted world of dromedaries in Africa, employing a structured approach. Initially, Sect. 9.1 delves into the origins and evolution of dromedaries on the continent, including the domestication process and their historical roots in Africa. Subsequent sections meticulously dissect the presence of dromedaries across various African countries, delineating their physiognomy, classification and unique characteristics, exemplified by detailed examination of populations in Algeria, Mali, Egypt, Niger, Nigeria, Mauritania, Chad, Kenya, Somalia, Ethiopia, Eritrea, Djibouti, Sudan, Libya, Tunisia, Morocco and other countries. Section 9.2 shifts focus to the organisational structures within the dromedary sector, exploring infrastructure, support systems and regulatory frameworks, while Sect. 9.3 scrutinises the structure and systems of dromedary husbandry, encompassing geographical distribution, breeding systems and production methodologies. Section 9.4 further elaborates on dromedary production objectives, covering primary production objectives, pharmacopoeia aspects, sociocultural roles and modern uses, including racing, trekking and other activities. Environmental implications, reproduction, prevalent diseases and biodiversity conservation efforts are comprehensively addressed in Sects. 9.5, 9.6, 9.7, and 9.8, paralleling discussions on dromedary diseases and biodiversity conservation programmes. Finally, Sect. 9.9 offers a concluding perspective, advocating for conservation measures and highlighting future directions for the sustainable management of dromedary populations in Africa.

9.1 Origins and Evolution of Dromedary in Africa

9.1.1 Domesticating Dromedaries

Dromedary domestication occurred somewhat late in human history, most likely at the transition between the second and first millennia BC. With the emergence of molecular markers, archaeologists have pieced together the domestication process of the dromedary. A significant reduction in the size of bone remains a growing association with human settlements and unambiguous artistic depictions in the fossil record from 2000 years ago. Dromedaries thus only cohabited with other domestic animals for a little over a millennium, at a time when their range was probably limited to the coastal mangrove habitats of the Arabian Peninsula, where their physiological salt requirements could be supported (Orlando 2016).

Today, dromedaries live mostly in the desert areas: North Africa, the Sahara and Sahel Regions, the Horn of Africa, throughout the Arabian Peninsula and the Levant (Fig. 9.1). A feral population also developed in Australia following their introduction in the nineteenth century AD (Orlando 2016).

Almathen et al. (2016) used spatial models of genetic diversity to decipher the history of dromedary domestication (Almathen et al. 2016). Because dromedary reference genomes have only recently become available, Almathen et al. (2016) used classic population genetic tools to characterise 1083 animals with 17 nuclear and mitochondrial microsatellites (Almathen et al. 2016). There were no phylogenetic patterns in mitochondrial DNA (mtDNA) data, as the two main haplogroups (HA and HB) were found throughout their range. As a result, it appears to be impossible to trace the central geographical location of the dromedary's domestication genetically from modern individuals, since a source of domestication should have the highest levels of genetic diversity. Dromedary movements along transcontinental trade routes may have eroded pre-existing phylogeographic models resulting from their initial domestication (Almathen et al. 2016). Alternatively, due to the animal's high dispersal abilities, it is possible that

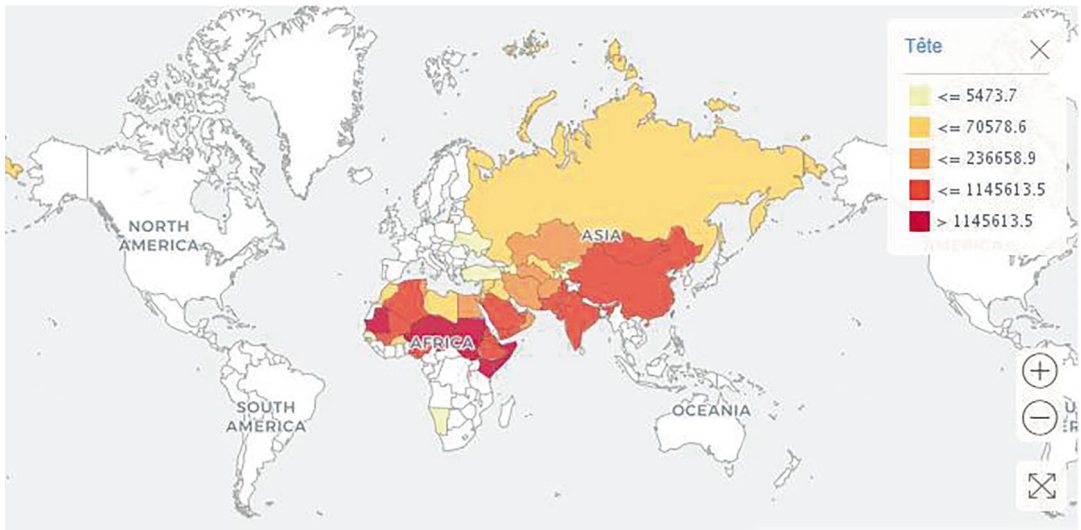

Fig. 9.1 Distribution of large camelids in the world. (From FAOSTAT 2019, licensed under Open Government License OGLv3.0)

such a population structure never existed in nature. In modern populations, detected haplotypes were found to be still segregating. Eight ancient specimens found were wild and dated from 5000 to 500 BC. Three more new haplotypes were discovered, indicating that the domestication process only captured a portion of the pre-existing diversity in the wild state. Data from ancient DNA recovered from wild individuals restricted to the United Arab Emirates (UAE), Middle East region, was unfortunately inconclusive with regards to the presence or absence of structure in Arabian Peninsula populations prior to domestication (Orlando 2016). The authors were able to calibrate the mtDNA clock to date significant population changes because the age of the old mtDNA sequences could be inferred from their archaeological context. This method takes advantage of the well-known benefit of old DNA data and time series in general (Orlando 2016). The authors were able to detect a massive population expansion about 600 years ago using a statistical software package that uses time-structured datasets to co-estimate the mtDNA clock and past demographic profiles. This date is consistent with the rise of the Ottoman Empire and the increasing use of dromedaries over long distances in an empire that extended from the coastal regions of North Africa to Arabia (Orlando 2016).

On the other note, Burger (2016) successfully identified south-eastern Arabia as the region of first domestication by analysing 7000-year-old bone DNA from wild and early domesticated dromedaries and comparing the results with genetic profiles of modern dromedary populations around the world (Burger 2016). The authors came to the conclusion that this domestication was followed by repeated crossing of wild camels with populations that had previously been domesticated. The dromedary's wild ancestor had a small geographic range and went extinct about 2000 years after the first domestication (Almathen et al. 2016).

9.1.2 Origins of the Dromedary in Africa

Modern camels belong to the order of Artiodactyla (even-toed ungulates), suborder Tylopoda, and the family of Camelidae, consisting of the tribes Camelini (Old World camels) and Lamini (New World camels), which diverged 16.3 (9.4–25.3) million years ago (Mya) (Wu et al. 2014).

Similar to other large mammals, the earliest-known ancestors of the camelid family, Protylopus, originated in the North American savannah during the Eocene (~45 Ma), with a size smaller than a domestic goat. At least 20 genera of camelids, such as Megacamelus and Procamelus, developed and disappeared again over the following million years (Honey et al. 1998; Rybczynski et al. 2013), until the ancestors of Old World camels reached Eurasia via the Bering land bridge around 6.5–7.5 Mya. Fossils of Paracamelus and other giant camels have been recorded in Asia (Kozhamkulova 1986; Flynn 1997), Europe (e.g. Spain (Pickford et al. 1995)), Northern Africa (*Camelus thomasi* (Peters 1998)) and the Arabian Peninsula (e.g. Syria (Martini et al. 2015)). The progenitors of the New World camels entered South America around 3 Mya (Rybczynski et al. 2013; Prothero and Schoch 2002) (Fig. 9.2).

The ancestors of dromedaries and Bactrian camels first appeared on the North American continent about 40 Mya. Camels (Lamini) on the New World level can be distinguished from dromedaries (Dromedary) on the Old World level. Dromedaries migrated to the eastern hemisphere via the Bering land bridge (the Old World). The split between one-humped and two-humped camels is thought to have occurred between 5 and eight million years ago. This contradicts previous theories, which suggest that the wild Bactrian camel was the direct and common ancestor of dromedaries and Bactrians. Furthermore, the observed prenatal development of the one-humped Arabian camels has refuted an earlier suggestion that the dromedary embryo undergoes similar developmental stages as the two-humped camels (Burger 2016).

While the genetic status of the two domestic species has long been established, the two-humped wild camel, *Camelus ferus,* was only recently recognised as a separate species based on molecular genetic data (Burger 2016). The demographic history of Old World camels derived from genomic drafts reveals the three species had

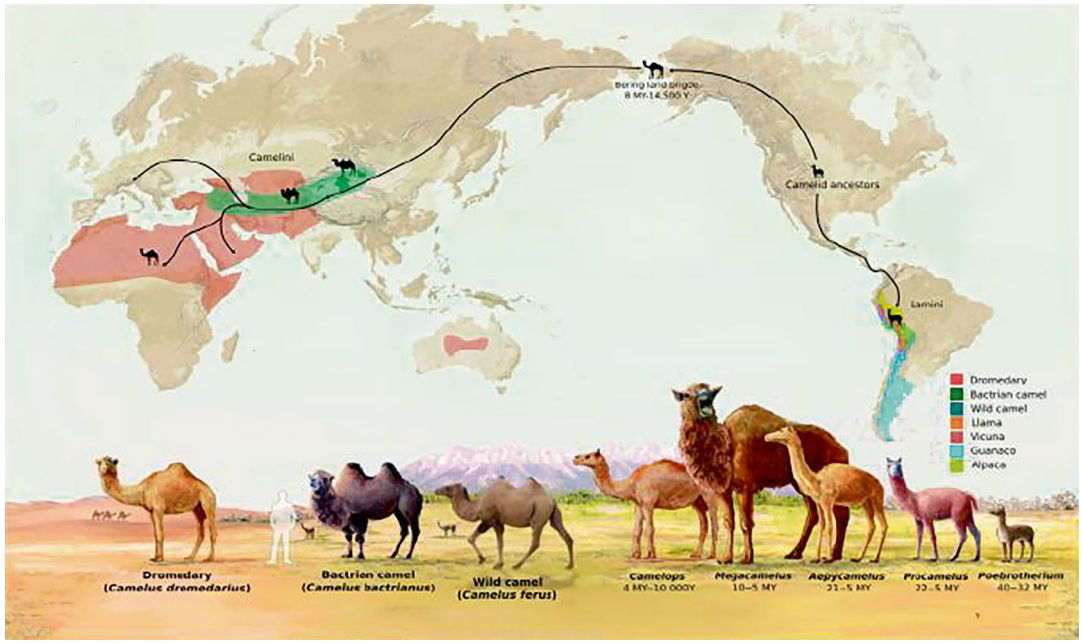

Fig. 9.2 Migration map of the historical camelid family. (From Burger et al. 2019, licensed under CC-BY 4.0)The current distribution of dromedaries and Bactrian camels is presented in red and green colours. The last refugia of the wild two-humped camels in China and Mongolia are shown as dark-green patches. The map was adapted from Mesa Schumacher/AramcoWorld (https://www.aramcoworld.com/en-US/Articles/November-2018/The-Magnificent-Migration). Reprint permits were granted by AramcoWorld on March 6, 2019

independent evolution over the past 100,000 years, with severe bottlenecks occurring during the last Ice Age and in the recent past. Wild two-humped camels are also excluded as direct ancestors of modern Bactrian domestic camels due to this long-term divergence (Almathen et al. 2016).

The dromedary, also known as the one-humped camel (*Camelus dromaderius*), represented a historic turning point for the human populations of the Arabian Peninsula, the Levant, North Africa, the Saharo-Sahelian region and beyond. According to Doutresoulle (1947), the dromedary was introduced into Africa through regular contact with the Arab world and established itself above the 14th north parallel, where the lack of glossines and horseflies, as well as the abundance of salty lakes, suited it perfectly (Doutresoulle 1947). The dromedary has expanded its range in Africa over the last 600 years, now being found in Senegal, Mauritania, Nigeria, Niger, Chad, Cameroon, the Magreb, Sudan and the Horn of Africa. The trans-Saharan salt trade was a significant activity that justified the continued presence of large herds of dromedaries in the desert. Dromedary rearing is very old in some countries, such as Niger, and is associated with typical sociological groups, such as pastoralists or nomads (Chaibou 2005). The introduction of the dromedary through contact with Arabs is true for almost the entire Sudano-Saharan deserts. Other introductions in Kenya and Namibia are believed to be more recent.

9.1.3 Dromedary in Africa

9.1.3.1 Physiognomy and Description of Dromedary Populations in Africa

The dromedary is the best-adapted pseudoruminant animal to the desert environment, characterised by scorching heat and extreme desiccation. Thus, its anatomy and physiology are different from other animals that live in a more aimable environment. In

addition to its role as a means of transport, the dromedary serves as a source of food and comfort for the inhabitants of the desert (Wilson 1999). They are a versatile, essential component of the desert ecosystem and a source of cheap animal protein for the indigenous population because they have the ability to convert the rare plant and cellulosic resources of the desert into milk and meat for human consumption, hence the interest in the domestication of this animal (Epstein 1971).

Camels are very distinct from other domestic animals by the presence of a broad head, a thin, long neck, small ears and wide, protruding eyes, wide and deep sinuses. The dromedary presents a lateral blind sinus sac, which is not observed in any other species. This allows the nasal passage to recover water at the time of exhalation. It also has an upperlip that is divided and very sensitive; a broad and low hang in the gearlap and its limbs are very powerful. Dromedary body varies in length from 220 to 250 cm and weight from 400 to 1100 kg, depending on the population (breed), with a life expectancy of 25 years (Wilson 1999). Doutresoulle (1947) identified in French West Africa a dromedary population with a height at withers of 170 cm for pack animals, 180–190 cm for loads and more than 200 cm for riding (Doutresoulle 1947).

One of the anatomical elements that clearly distinguish the dromedary from ruminants and other herbivorous species is the nature of its wide and elastic legs, which are well-suited for sandy soils. The hump is mostly comprised of adipose tissue of soft consistency that vary in volume with the nutritional status of the animal. The digestive anatomy of the dromedary differs from that of other animals in terms of structure and function. It is particularly suited to the natural plant resources of desert environments, including thorny plant species inaccessible to other herbivores (Djomtchaigue et al. 2015). The animal has glands behind the head that are used for perspiration. The skin is supple and covered with hair. The female has four quarters at the level of the udder, while the males' testicles are positioned high behind the thighs (as in cats and dogs). These morphological and anatomical features explain the adaptation capacity of the dromedary in desert environments with extreme temperatures (Epstein 1971).

The dromedary has a physiology entirely focused on anticipating periods of food and water shortages. The mechanisms of adaptation to dehydration are complex in this species. These could be evaluated by a very large set of parameters which, when combined, give this unique behaviour among domestic species. The dromedary's resistance to dehydration and heat is proverbial. In fact, this feature, which has long intrigued researchers, is one of the most studied aspects of the dromedary, especially with the advent of global warming (Epstein 1971). The physiology of the dromedary is tuned for survival in difficult conditions. In a state of dehydration, the animal is able to save body water by mechanisms that reduce water losses (decrease in diuresis, stop sweating, decrease in basic metabolism, change in body temperature) while maintaining a homeostasis vital to its survival, both by limiting the variation in the concentration of vital parameters and by ensuring maximum excretion of metabolic waste. This is demonstrated by the emission of highly concentrated urine. However, the excretion of elements requiring large quantities of water (glucose, urea in particular) is strictly controlled. These adaptation mechanisms, which are the hallmark of the dromedary, also explain why it is one of the domestic species that has not left its natural home range (Bengoumi and Faye 2002).

Because dromedaries generally bear the names of the tribes that keep them, we can find several populations in different tribes with not much recognisable difference. Modern classifications have made little progress beyond these concepts, as little effort has been made in conventional breeding and genetic selection, or to attribute quantitative production parameters that are now so important in other species for the description of the breed. The current quantitative approach uses six morphological and biological characteristics, such as habitat, function and geographic distribution, physical size based on linear measurements, ease of treatment and speed of weight gain as parameters in the description of the breed. In Saudi Arabia, the most commonly used clas-

sification is based on coat colour, as is done on dromedary populations in Algeria and other North African countries (Cherifi et al. 2013; Harek et al. 2017). The colour variants vary from one region to another, but it is not yet clear whether there are differences in production between or among colour types. While light-coloured animals from Sudan are particularly appreciated for their speed, pastoral camel keepers have an overall assessment of their animals based on morphological, phaneroptic and metric parameters, in particular height at the withers (Doutresoulle 1947; Djomtchaigue et al. 2015). It is possible that, with a well-designed and funded programme, the constraints of low fertility and the difficulty of breeding dromedaries can be significantly reduced. There are sufficient variations in body weight at maturity, conformation characteristics, working capacity and production potential to make genetic improvement possible, and improved husbandry and health management can reduce camel calves' mortality. However, studies conducted by Almathen et al. (2016) on global populations and Cherifi et al. (2017) on North African populations show that the populations studied are very close genetically and that no structuring into populations could be clearly observed (Almathen et al. 2016; Cherifi et al. 2017).

9.1.3.2 Classification of Indigenous Dromedary Populations

Globally, high variability is observed among dromedary populations, although great confusion is reported. Chapter 1 of this book states that the total number of African dromedary camel breeds is 63, distributed respectively as follows: 23 breeds in Eastern Africa, 3 breeds in Central Africa, 23 breeds in Northern Africa, 2 breeds in Southern Africa and 12 breeds in Western Africa. Indeed, several breed names exist, but more than one breed name could represent the same animal genotype. In an earlier report (Blanc and Ennesser 1989), 48 breeds of dromedaries were described worldwide and classified into eight subgroups according to their physical attributes, but this classification was only based on the general conformation of the animals.

Dromedaries were also classified into two major classes: ride and pack dromedaries. This classification was suitable to satisfy the needs of caravans, transport and military purposes during the first half of the twentieth century. A new system of classification was proposed based on the fact that the dromedary is a major component of the agropastoral systems in vast pastoral areas in Asia and Africa. Dromedaries have also been classified into four major classes: meat, dairy, dual-purpose and race dromedaries (Wardeh 2004). However, the keepers of dromedaries or owning tribes have their own system of classification or nomenclature, which is based, in general, on the owning tribe, colour and region (Cherifi et al. 2013; Harek et al. 2017).

There is great confusion in the description of the biodiversity of camels, as mentioned by many authors and attested by results using molecular genetics tools. Thus, the different phenotypes described in Kenya, Tunisia, Chad, Egypt and Algeria have little or no significant genetic differences between them (Cherifi et al. 2017; Djomtchaigue et al. 2015; Jianlin et al. 2000; Chniter et al. 2013; Harek et al. 2015). In Saudi Arabia, nine dromedary phenotypes were described, but after molecular genetics analysis, only three subtypes were identified (Almathen 2014; Faye and Porphyre 2011). The camel phenotypes described in these countries are presented below. However, additional molecular genetic analyses will help in classifying the populations into distinct breeds or genotypes.

9.1.3.3 Algerian Dromedary Populations

In Algeria, dromedary populations are named according to ethnicity or geographical area. Within each ethnicity, the keepers name the populations according to coat colour (Cherifi et al. 2013; Harek et al. 2017). Seven camel populations named according to coat colour in Algeria are shown in Fig. 9.3a–g and described below.

Hamra

The Hamra has a dark red or brown uniform coat colour (Fig. 9.3a). This type of coat is very appreciated and highly valued by farmers. The

brown uniform coat is preferred by some farmers for reasons including aesthetics, religion and sometimes commercial (for cloth making). Other farmers consider the dromedary with the red coat as best suited to the environment, especially in terms of disease resistance and drought tolerance. Hamra's coat is very appreciated because of its hair quality, which makes it suitable for the manufacture of many traditional items. The Hamra accounts for about 30% of the dromedary population in Algeria and about 47% of the population in Tunisia in 2009 (Ould Ahmed 2009). The difference in proportion between the two regions is probably due to the decline of the craft in Algeria.

Safra

The Safra Camel has a yellowish uniform coat colour (Fig. 9.3b). It constitutes about 27.5% of the dromedary population. This coat colour is among the most favoured by farmers (Ould Ahmed 2009).

Chegra

Chegra dromedary has a clear reddish coat (Fig. 9.3c). It is found across the southwest of Algeria, constituting 11% of the dromedary population. This coat is not very popular amongst farmers.

Beydha

Beydha dromedary has a white or very light grey coat colour on its entire body (Fig. 9.3d). Beydha is characterised by its strong and sometimes aggressive behaviour and its susceptibility to diseases.

Zarga

The coat colour of Zarga is completely black (Fig. 9.3e). This phenotype is less preferred when compared to the other phenotypes. Individuals with this coat are not susceptible to disease. The polymorphism of the Zarga (black) coat colour occurs at a frequency of 7.5% in the study area compared to a frequency of 6% in Tunisia (Ould Ahmed 2009). These frequencies suggest that the trait is recessive in nature and is favoured by natural selection.

Hajla

Hajla is characterised by white colour on the head and legs and a light yellowish colour on the body (Fig. 9.3f). Animals with this coat colour are highly appreciated aesthetically and considered by the farmers to attract or draw luck. It is, however, very rare, with a low frequency (9.5%) on farms, which may be attributed to natural selection drivers.

Zarwala (Azargaf)

The coat of Zarwala is a mixture of blue, white and black (crossbred) (Fig. 9.3g). It is less appreciated by farmers. The dromedaries of this colour are characterised by a severe form of deafness. Theories suggest that white spots are linked to the domestication process and are sometimes associated with health disorders (Holl et al. 2017).

The significant variations in the colour of the coat (Hamra, Safra, Beydha, Chegra, Zarga, Hajla and Zarwal) of the Algerian camel populations indicate an admixture of different genetic backgrounds. The high frequency of the red colour appears to be a criterion for adaptation to the arid environmental conditions of Algeria. This hypothesis needs to be carefully studied in order to establish a relationship between adaptation and the mechanisms of the dromedary's coat colour variations in Algeria.

Many socio-geographical factors are used to distinguish between different dromedary populations in Algeria. The notations are linked to the geographical area or tribe to which the animal belongs. Indeed, the dromedary populations in Algeria are also named after five geographic locations (Fig. 9.4a).

Targui

Targui, as the name indicates, is an animal raised by the Tuareg. It is an animal with strong muscular legs and a little bump (Fig. 9.4a). It is considered an excellent animal for racing. The coat is

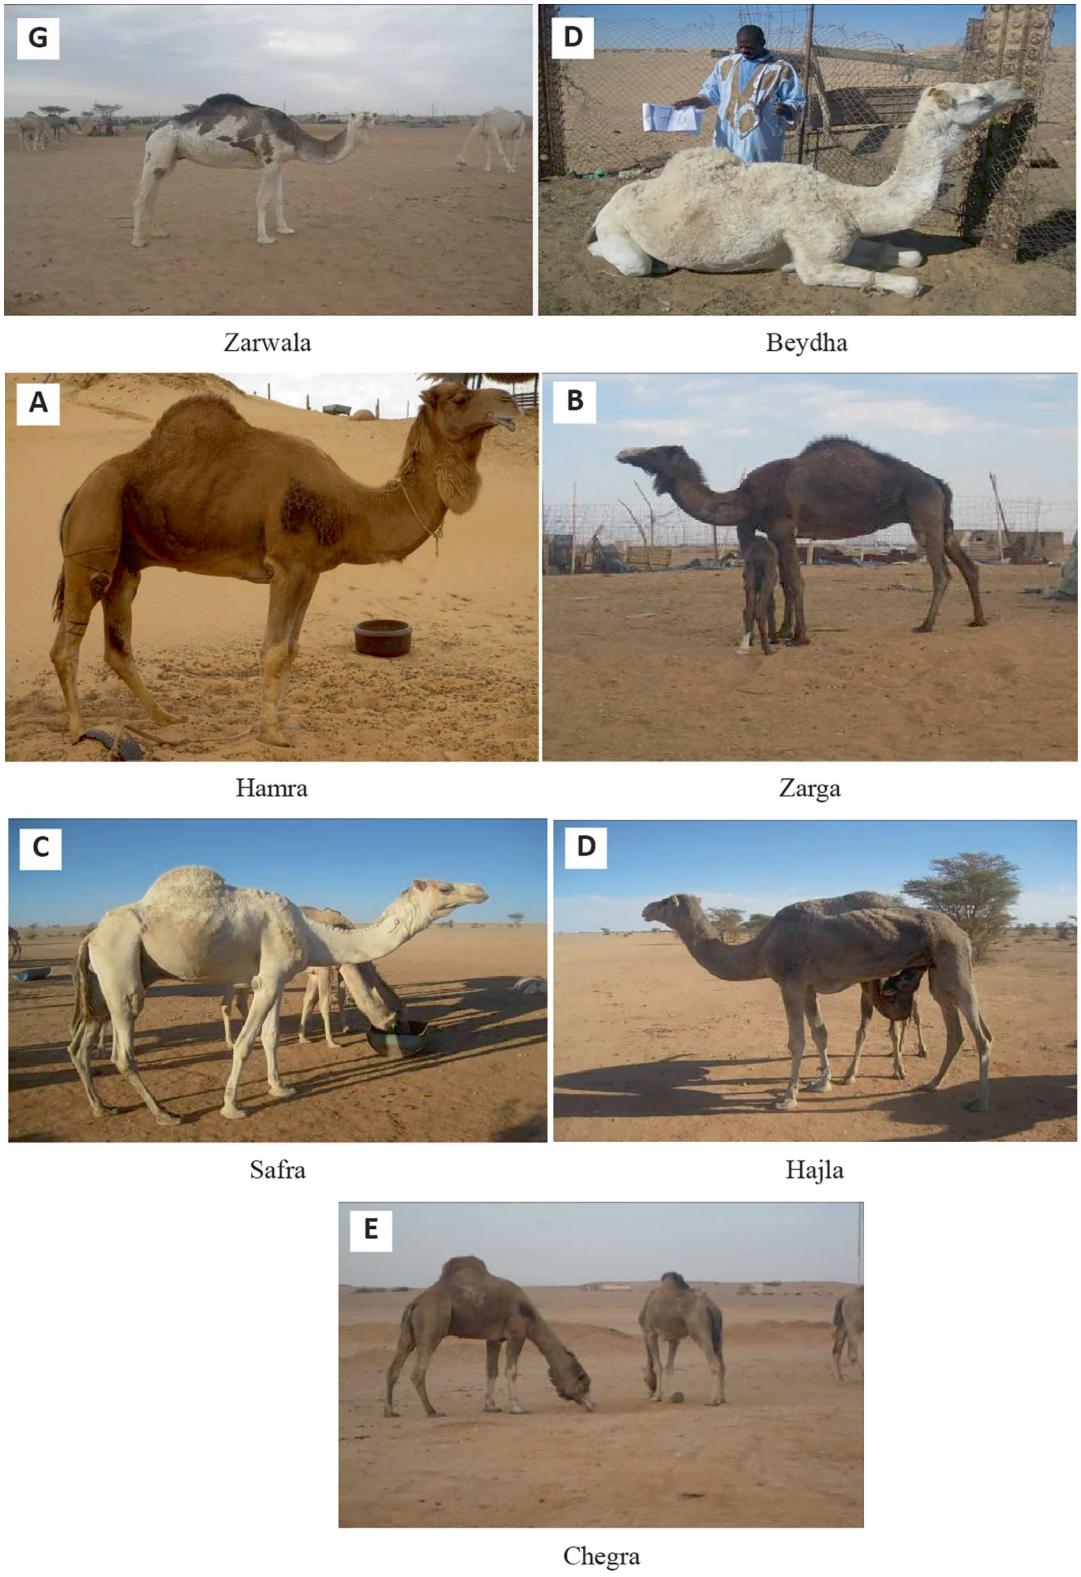

Fig. 9.3 Major coat colours found in dromedary populations in Algeria. (Photos by Gaouar S.B.S)

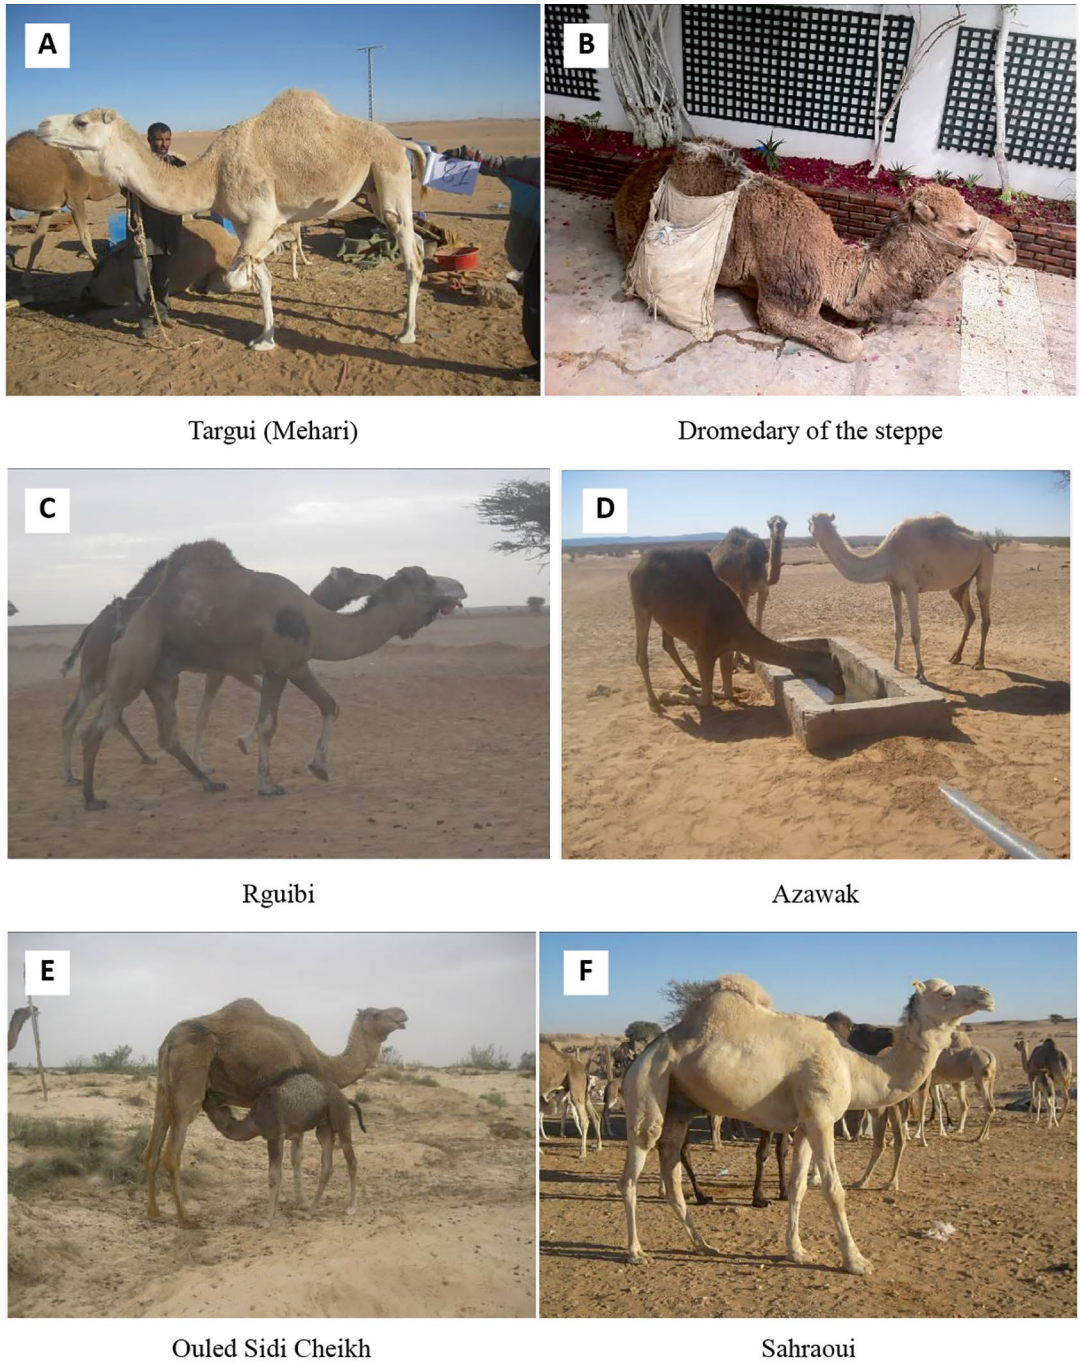

Fig. 9.4 Dromedary populations in the southwest of Algeria. (Photos by Gaouar S.B.S)

usually light beige. The Targui is mainly used for tourism, especially in the regions around the Hoggar and Tassili areas. It is sometimes used for cross-breeding with other populations, depending on the desired characteristics.

Dromedary of the Steppe (Naili)
The animal raised by the tribe of Ouled Neil (Djelfa Wilaya) is found in the Saharan borders and especially at the edge of the Steppe and the Sahara. The population is in decline. It is a relatively small dromedary and a poor carrier (Fig. 9.4b). But it is very appreciated for the quality of fur, especially for making traditional items.

Rguibi
Rguibi or Mniae is the local type raised in the area of Bechar and Tindouf by the Rguibet and Mniae tribes of Yemeni origin. It has multiple abilities with medium production of meat and milk and excellent adaptation to different eco-climatic conditions. Rguibi is characterised by various size variants (light to heavy) and fur (medium length) (Fig. 9.4c). This population is found in the extreme south of Ain Safra, south of Algeria, and the extreme northeast of Mauritania and northwest of Mali (Wardeh 2004).

Azawak
Azawak is the riding dromedary for the Tuareg from Niger and Mali. It is suitable for racing. It is slender-looking, light-coloured (light brown) and hairless (Fig. 9.4d). There are many different types depending on the nuances of the coat; it was introduced by the Tuareg farmers, and it is found throughout the southwest of Algeria (up to Timyaouine Ain Safra).

Ouled Sidi Cheikh
Ouled Sidi Cheikh (Fig. 9.4e) is found in the highland regions of Algeria, and it is less appreciated by the farmers in the south. It is adapted to a climate marked by a dry summer and a very cold winter.

Chaambi
Chaambi is characterised by a short stature, corpulence and robustness in saddled transport. It is the animal of the peasant, the auxiliary of the oasis dwellers. It is commonly used for agricultural work and appreciated for its meat. It is found throughout North Africa but mainly in Tunisia and eastern Algeria (CIRAD 2022).

Sahraoui
Sahraoui (Fig. 9.4f) was obtained from a cross between Chaambi and Ouled Sidi Cheikh. Its territory extends from all the Grand Erg Occidental of the Sahara (north of Adrar). It is a breed with lactation performance under intenisf or semi intenisf systems (Chergui et al. 2023, 2024).

Ayat Al-Khabbash
Ayat Al-Khabbash are well-developed pack animals that respond to fattening. They are found throughout North Africa, but mainly in Tunisia and eastern Algeria, and are raised by the tribes in Southern Algeria (Wardeh 2004). Unfortunately, this population seems to have become extinct (Cherifi et al. 2013).

9.1.3.4 Mali Dromedary Population

Traoré et al. (2014) identified two classification systems of dromedaries by Gurma and Hausa herders (Traoré et al. 2014). The Hausas classify them into two types (the Tilabayaten and the Talmorokit) on the basis of the overall conformation, production ability (milk, speed, draught) and colour. The Tilabayaten is described as white or light grey, with a slender body shape. Its milk production is reported to be higher than that of the Talmorokit. This type has a dark coat and is relatively smaller. Its heavier conformation makes it suitable for the transportation of goods. Nine types are described by the Gurma herders. Seven are distinguished and named on the basis of coat colour, similar to the classification in Algeria described earlier. It includes the Azargaf, characterised by its piebald colour and blue eyes. The two remaining types are the Adignas, which means 'trustable animal', and the Awinag, which is characterised by its totally white colour and a vision defect.

No definite inventory of dromedary breeds or types in Mali is available. The types cited in Hausa are all included in the list of 12 types reported by Ouologuem et al. (2004). The Abzaw and Azargaf types might correspond to the Abzin and Azaghaf types described by Chaibou (2005) in Niger (Chaibou 2005). This proposition is based on the similarity in the names used as well as the respective coat colours of these types.

9.1.3.5 Egypt Dromedary Population

Four dromedary breeds, Sudani, Maghrabi, Falahi (or Fellahi or Baladi) and Mowalled, are recognised in Egypt (Cherifi et al. 2017). Nowier et al. (2020) also cited Somali as a breed reared in Egypt (Nowier et al. 2020). The Al-Delta strain is found in the Egyptian Delta, used mainly for agricultural draft and transport (Nowier et al. 2020). This Delta dromedary is not a distinctive breed in the real sense but a general-purpose dromedary that was developed with a considerable intake of green feed and water. It attains a large size with well-developed muscles, which allows it to carry heavy loads and be suitable for various agricultural functions (Wardeh 2004).

Maghrabi

Maghrabi is found in the coastal regions of Northern Africa that extend from Egypt to Morocco. The Maghrebi generally refer to several strains of dromedaries which vary in size, body conformation and colour. It is believed to be a mixture of the Sudanese, Egyptian, Libyan and Tunisian dromedaries. The Maghrebi dromedary is medium in size with a small pointed hump. Besides pack use, the Maghrebi dromedary is used for all kinds of agricultural, industrial and draft purposes. It generally responds to feeding and might gain about 700–1000 grams per day during the first year under intensive conditions (Wardeh 2004).

Al-Fellahi or Fellahi

Al-Fellahi dromedary breed is kept by farmers along the Nile in Upper (Southern) Egypt, from which it derived its name. Al-Fellahi dromedary is characterised by its heavy bones and muscles, big size and its slow pace. It is generally used in agricultural work and transport. It also responds to fattening (Wardeh 2004).

9.1.3.6 Niger and Nigeria Dromedary Populations

Doutresoulle (1947) associated various morphotypes of dromedaries with Niger and Nigeria. However, there is not enough information for their rigorous classification (Doutresoulle 1947). Niger has one of the fastest-growing dromedary population, doubling in the last few decades in regions where erratic rainfalls has led to the regression of other domestic livestock species (Chaibou 2005). Abdussamad et al. (2011) have classified different dromedary ecotypes based on coat colour under the Azawak dromedary breed (Abdussamad et al. 2011). Though the dark-brown ecotype was the most preferred, their study indicated that there is likely a survival strategy that sustains pastoral life in a fragile ecosystem, which largely depends on the complementary performance of an assortment of dromedary ecotypes at different seasons of the year.

Azawak

The Azawak dromedary is prevalent in semi-arid northeastern Nigeria. It is an important pack, ride, dairy and meat animal. The dromedaries were made up of predominantly mixed breeds originating from Eastern and Northern Africa regions (Jaji et al. 2017).

9.1.3.7 Mauritania Dromedary Population

Al-Jandaweel (Gandoil)

The Al-Jandaweel dromedary is found in Southern Mauritania along the Senegal River. These Al-Jandaweel dromedaries are not typical lowland reverine types, though they are suspected to have diverse origins. They are dark-coloured, heavy animals mainly used for draft. The feed availability in the Senegal River valley might have resulted in the development of this heavy dromedary (Wardeh 2004).

Mehari (Mehri)

The Mehari is a thoroughbred race dromedary that descended from the Murrah dromedaries in the Sultanate of Oman. They are beautiful, light-coloured and very famous race dromedaries in the Sahara. The colonial French troops formed the Meharist corps based on this breed. They used the Mehari dromedaries for riding and divided them into three categories according to height at the withers. Dromedaries that were 190–200 cm high were used by officers, while those 185 cm high were ridden by the ranks and files. Shorter dromedaries that were at least 180 cm at the withers tall were used as pack animals (Wardeh 2004).

9.1.3.8 Chad Dromedary Population

According to Martin et al. (1996), dromedaries are mostly raised in the Manga and Kanem regions in the Lake Chad Basin, east of Niger and in western Chad (Martin et al. 1996). The two other countries sharing Lake Chad, Cameroon and Nigeria, have few dromedaries. Around Lake Chad, numerous changes in production systems consequent on the recent climatic changes are happening. Thus, the relative development of dromedary production and the increases in the dromedary products' trade have resulted in a broader distribution of various types. It is possible, however, to classify the dromaderies found in this region into four major groups. The dromedary population in Chad is close to 2.5 million heads. Breeds are classified based on their coat colours, which is also not very defendable in a genetic context (Djomtchaigue et al. 2015). Although there has been no genetic characterisation of these groups, they have distinct morphological characters and occupy well-defined geographical areas (Fig. 9.5).

Tibesti

Tibesti breed was probably introduced by Toubou pastoralists from Borku and Tibesti. This is a mountain breed with a withers height of 1.75–1.85 m used as a pack and riding animal. The coat colour varies from grey to dark brown, and the Tibesti dromedary is found mainly in the Kanem region of Chad.

Manga

Manga dromedary breed is 1.85–2.00 m high at the withers and found mostly in the Chadian plains. It weighs 550 kg, well-muscled but not very hardy. The colour is fawn or reddish, and this breed is kept mainly for meat, especially in the Bornu region of Nigeria and in the northern zone of Lake Chad. Another breed called the Komadougou has been described, which seems

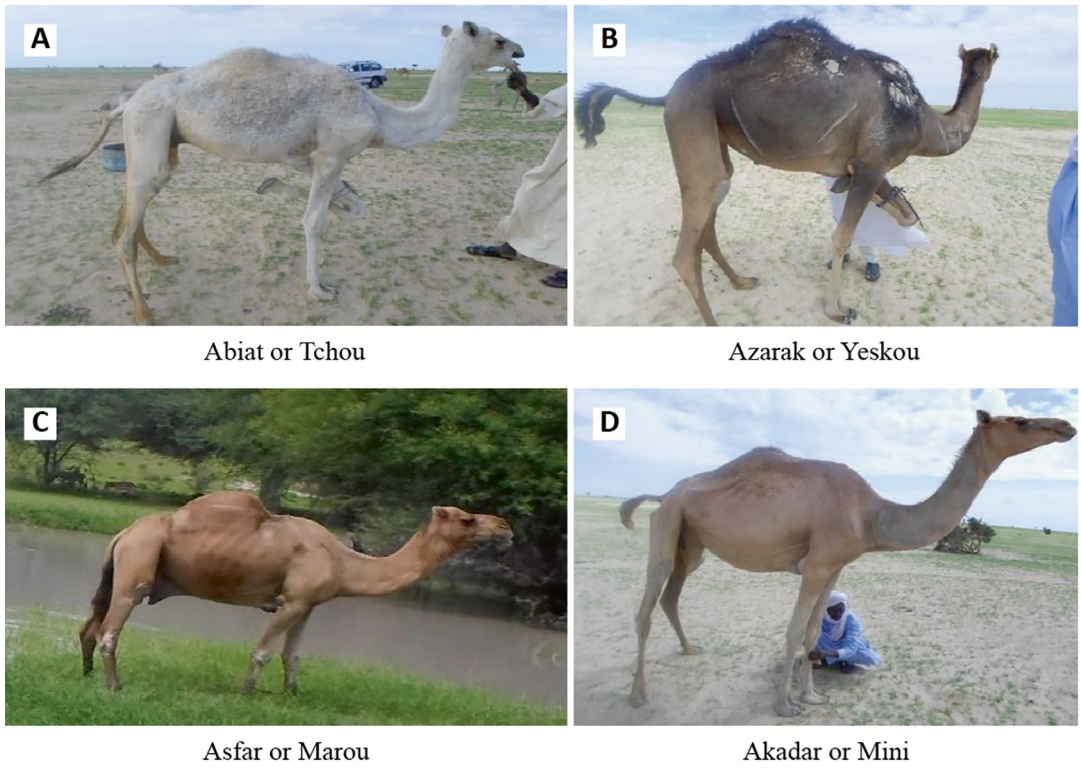

Fig. 9.5 Coat colours as they are called by Chadian dromedary herders. (From Djomtchaigue et al. 2015, licensed under CC-BY 4.0)

similar to the Manga. This breed is considered to be a meat and transport animal found amongst the Fulani people in Nigeria.

Touareg

The Touareg breed originates from the Aïr but is also present in the Lake Chad Basin. It is described as a mountain type with 1.85–1.90 m high at the withers, weighs about 370 kg and is very light or pied in colour. This light breed is mainly used as a saddle animal in the search for grazing areas and for social visits.

Arab

This breed is common in the mountains and plains. It is very large, weighing about 450–500 kg. The colour is pied or greyish, and it is used as a pack animal. It is found in the Arab settlement area of the Convention Basin. The typical coat colours for breeds are indicated in Fig. 9.4.

9.1.3.9 Kenya Dromedary Population

The Somali, Turkana and Rendille/Gabbra are the three dromedary breeds in Kenya (Mburu et al. 2003). A fourth called Pakistani was imported from Pakistan into Laikipia ranches in Kenya in the early 1990s. Only a few of these pure Pakistan camels now exist; instead, their crosses with Somali or Turkana breeds have spread from Laikipia to Samburu, East Pokot, Kajiado, Northern Tanzania, Mandera and Marsabit districts (Kuria and Walaga 2008). A description of these breeds is presented below.

Somali

The Somali breed is a dairy type which can yield 3–5 litres of milk daily. Milking the dromedary three times daily guarantees more milk. First calving occurs between 4 and 5 years of age, and lactation could last 1–1.5 years post-calving. The coat colour of Somali is cream/brown (Fig. 9.6), and it weighs about 450–850 kg at maturity with an average standing height of 2 metres. The Somali requires about 8–12 h of feeding time per day, depending on feed availability. It is more comfortable while feeding on shrubs because of its height. Early maturity and high milk production are two important advantages of this breed, while poor adaptability to rough terrain and rocky hillsides due to its large size is its main disadvantage. It also suffers more with low feed availability (Kuria and Walaga 2008).

The Somali breed has four subtypes, namely, Hoor, Siftarr, Aidimo and Gelab, which differ in physical appearance, production and adaptability characteristics. While the Hoor is the highest milk-producing subtype, it is the least hardy. Gelab, on the other hand, is the smallest in body size and the least milk-producing, but the hardiest.

Rendille/Gabbra

The Rendille breed produces an average of 1–3 litres of milk per day with a lactation length of 1–1.5 years, and first calving occurs between 5 and 6 years of age. The coat colour is cream or brown (Fig. 9.7) with a mature live bodyweight around 550 kg. The average standing height is 1.8 metres. Its feed requirement is less than the Somali breed, needing 8–10 h of grazing per day. This breed does better under poor pasture conditions and rough terrain and tolerates drought conditions better than the Somali breed. However, it has a lower milk yield and matures later (Kuria and Walaga 2008).

Turkana

The Turkana breed produces about 1–2.5 litres of milk per day, which is lower than what the Somali and Rendille/Gabbra breeds produce. The first calving occurs between 5 and 6 years of age, and it lactates for about 1 year after calving. The body colour is mainly greyish/dark (Fig. 9.8). It is a late-maturing breed, attaining a mature live bodyweight around 250–500 kg and an average standing height of 1.7 metres. It requires about 7 h of grazing. It is the hardiest of all the breeds, agile and able to climb steep hills because of its small body size. It is able to cope better with feed scarcity.

9.1.3.10 Somalia Dromedary Population

Somali

Somali dromedary breed is commonly found throughout Somalia. The adult males average 650 kg and the females 575 kg. The average lactation yield is 1650 kg (Fig. 9.6) (DAD-IS 2021).

Fig. 9.6 Somali dromedary. (From Tilahun et al. 2020, licensed under CC-BY 4.0)

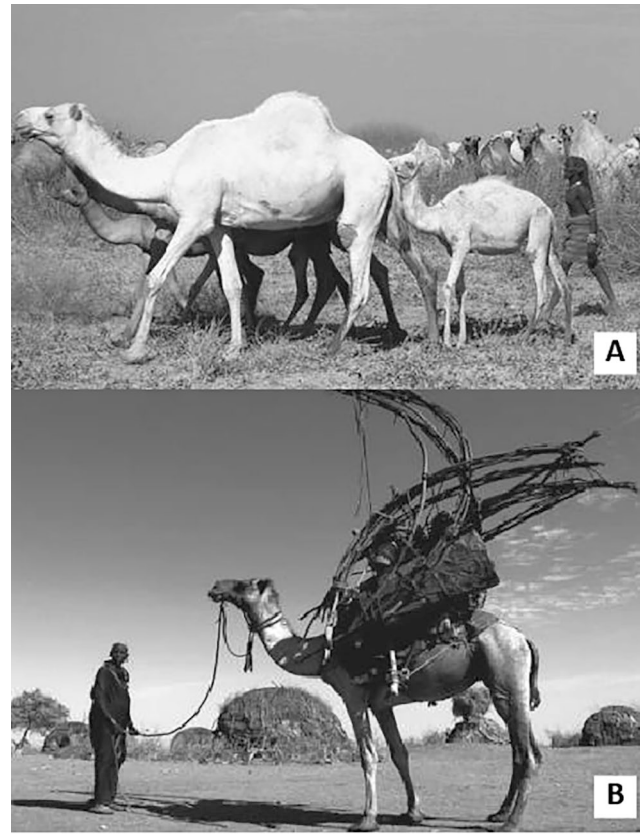

Fig. 9.7 Rendille dromedary. (From Sun 2005, licensed under CC-BY 4.0). (**a**) A warrior driving camel herds out of the camp for day's herding. (**b**) Transporting wedding goods

Afar

The Afar breed is also commonly found throughout Somalia (Fig. 9.9) (DAD-IS 2021).

Sifdar

Sifdar breed is found in the lower Shabbily river belt in Somalia. The breed is tall, light and with grey to reddish for coat colour. It reaches matu-

Fig. 9.8 Turkan young camels with female, in Prosopis thicket at lake, Northern Turkana. (From Carr 2017, licensed under CC-BY 4.0)

rity at 5–6 years but is able to reproduce at 6–7 years. This breed slowly loses weight during the dry season and is relatively resistant to biting flies. Sifdar dromedaries produce about 4 kg of milk daily (2–6 kg) and about 1000 kg over a period of 6–10 months (Wardeh 2004).

Eyddimo

The Eyddimo dromedary breed is distributed in the Bay, Gedo and Juga regions of Somalia. They are tall, heavily built, with a relatively bigger hump, long necked, white-coloured and having Roman nose. Eyddimo dromedaries have a slow rate of weight gain during the wet season and slow weight loss during the dry season. They mature at 7–8 years of age, produce about 1000 kg of milk during 6–10 months (4 kg/day) and are very susceptible to biting flies (Wardeh 2004).

9.1.3.11 Ethiopia Dromedary Population

According to Legesse et al. (2018), there are eight breeds in Ethiopia as Jigjiga, Issa, Hoor, Ayden, Liben, Borena, Kerreyu and Afar (Legesse et al. 2018). Wilson (2020) confirmed that the genetic dromedary resources are also generally referred to by the name of the ethnic group owning them and the colour of their coat in Ethiopia and Eretria (Wilson 2020).

9.1.3.12 Eretria Dromedary Population

According to Dioli (2006), the classification of Eritrean dromedaries is based on dromedary-owning tribes, coat colour, region/location, and cultural or social functions (Dioli 2006). However, dromedary breeds have not yet been evaluated based on their performance (Wilson 2020). The four regional populations found in Eritrea are as follows: Gash-Barca, Anseba, Northern Red Sea and Southern Red Sea. The dromedaries of the western lowlands of Eritrea have much in common with those of the Sudan, while those of the eastern lowlands are identical to the dromedaries of the Afar region in Ethiopia, for this breed is transboundary (Gebrehiwet 2021).

9.1.3.13 Djibouti Dromedary Population

Djibouti is a country enclosed between Eritrea, Ethiopia and Somalia, so the breed description follows the same situation as cited for these countries and cited by Dioli (2006) and Wilson (2020).

9.1.3.14 Sudan Dromedary Population

Sudanese dromedary ecotypes include the Shanbali, Kenani, Maalia, Maganeen, Butana, Kabashi and Lahwee, and they have similar

Fig. 9.9 Afar dromedary in Afar Region, Northeast Ethiopia (Melkamu et al. 2022). (From Melkamu et al. 2022, licensed under CC-BY 4.0)

morphological characteristics (Ishag et al. 2011). They have either grey, brown or yellow coat colours. They have a large body conformation and a well-developed large hump with medium-sized udder and teats. Pack dromedaries are the ecotypes that make up the majority of this heavy group. Despite being classified as 'pack dromedary', the Rashaidi dromedary animals have different phenotypic characteristics from the above. They have dark grey or pinkish red coat colour; they have a light weight, with a shorter shoulder height than earlier ecotypes. The Anafi and Bishari breeds, on the other hand, are classified as riding and racing dromedaries, and they have similar characteristics (white, yellowish coat colour, light weight). The Arabi dromedary (Shanbali, Kenani, Maalia, Maganeen and Lahwee dromedary) has better performance and higher milk production and is considered a dual-use dromedary (meat and dairy). Wardeh (2004) described some breeds not cited by Ishag et al. (2011). These breeds are Shallageea and Aririt.

Shallageea

The Shallageea dromedaries are found along the Red Sea coast in Northeastern Sudan. They are tough and eat mostly 'salty Adlib' or Shrubby Seablite (*Suaeda fruticosa*) as well as other mangrove plant species leaves and fruits. The Shallageea are experts at walking into the sea and nipping the lemon-like fruits from mangrove bushes. They frequently wade so far into the water that only the head and hump are visible above the surface. The Shallageea are excellent dairy types, especially during the ad lib fruiting season in November, March and July. One dromedary can give up to 6 kg of milk during early night milking. It may give another 3.5 kg 3 h later. The morning milk could then amount to 6–7 kg. With three milkings per day, each animal may give a daily yield of 15–18 kg. During a rainy period and excellent pasture, an animal can produce 18–21 kg of milk daily (Wardeh 2004).

Aririt

The Aririt dromedary breed is found in the western vast plateau of the Red Sea hills of Aulib in Sudan. This breed is endurant; it can cover long distances at a steady pace without water. The Aririt is also a fair dairy type. Under good conditions, animals may give up to 2.5–5 kg of milk at midday and evening milking and 3.5–5 kg in the morning. The volume of milk production depends on the feeding resources made available (Wardeh 2004).

Kenani Dromedary

The Kenani breed is also known as the Rufaa dromedary. Rufaa, Agilieen, Dighame and Kenana tribes own the breed, which is found in Sinnar and Blue Nile states. Kenani dromedaries have average barrel girth, chest girth, height at shoulder, and body weight, respectively, of 2.48 ± 0.23 m, 2.07 ± 0.10 m, 1.95 ± 0.08 m, and 492 ± 71.0 kg, respectively. The dominant coat colours of these dromedaries are dark brown, grey and yellowish. They are distinguished by long hair that covers the entire body, particularly on the hump and neck. The hump is well-developed in these dromedaries, and it is located in the middle of the back. The udder and teats are medium to large in size, and the milk vein is well-developed. Dromedaries are usually found in the south and north of Sinnar state during the dry seasons (winter and summer).

Rashaidi Dromedary (Rachaida)

The Rashaida nomadic tribe migrated from Saudi Arabia to Sudan and bred the dromedaries in Eastern Sudan (Gadaref and Kassala states). Dominant coat colours are dark grey and pinkish red. These dromedaries'average barrel girth, chest girth, shoulder height and body weight are 2.56 ± 0.23 m, 1.94 ± 0.08 m, 1.76 ± 0.07 m and 423 ± 65.9 kg, respectively. The animals from this type are distinguished by their shorter height at the shoulders, heavier weight and exceptional ability to survive in drought conditions (harsh environment). They have short to medium hair and a small hump, as well as a large and well-developed udder and teats. These dromedaries can be found in Al-showak and Gabat Al-feel (Gadaref state) during the dry season, and they migrate north from New Halfa town (Kassala state) in the wet season.

Lahwee Dromedary

This Lahwee is kept by the Lahween tribe in Gadaref state. This breed is mostly found in Al-showak and Gabat Al-feel areas but migrates to Al-soubag area in the wet season. The average barrel girth, chest girth, height at shoulder and body weight of the Lahwee dromedary are 2.51 ± 0.20 m, 1.98 ± 0.08 m, 1.84 ± 0.07 m and 444 ± 50.7 kg, respectively. The coat colours common in this breed are brown, red and yellowish. The hair is of medium length, the hump is centrally located with an erect or side-bending orientation with a medium size udder and teats.

Anafi Dromedary

The Anafi dromedary can be found in Gadaref state in Eastern Sudan amongst the Rashaida and Lahween tribes. In Gezira state in central Sudan, Anafi is by the Shukria Bataheen and Ahameda tribes, and in Sinnar state in central Sudan, Anafi is also found among the Rufaa and Kenana tribes. This breed is kept in small herds and mixed with other types of dromedaries. The barrel girth, chest girth, height at shoulder and body weight of an Anafi dromedary are 2.39 m, 1.95 m, 1.84 m and 416 kg, respectively. Anafi predominantly have white coat colour, but yellowish animals are also found. It has short and soft hair with a small erect hump in the middle of their backs. The animals have small-sized udders and teats.

Bishari Dromedary

The Bishari breed is mostly found in Eastern Sudan. It is kept by the Bishareen, Amarar, Beni Amir and Hadendowa tribes. Their average barrel girth, chest girth, shoulder height and body weight are 2.36 m, 1.94 m, 1.84 m and 410 kg, respectively. Their coat colour is white or yellowish with short hair and a concave face. The hump is small to medium in size, erect, and sits in the middle of the back. Bishari dromedary udders and teats are characterised by their small size.

Kabbashi Dromedary

The Kabbashi breed is found in North Kordofan state, where it is kept by the Kababish tribe. It has an average barrel girth, chest girth, height at shoulder and body weight of 2.25 m, 1.98 m, 1.91 m and 451 kg, respectively. The primary coat colours of this breed are grey, red and yellow. The hair is medium to long in size, the hump is small, erect and located in the middle of the back, and it has medium-sized udders and teats. The Kabbashi dromedary shares characteristics with the

Kawahla and Hamar dromedaries. During the dry season, the owners of these dromedaries live near Al-obied town, and during the wet season, they relocate to the north (Soudari area).

Maganeen Dromedary

The Maganeen dromedary breed is reared in Northern Kordofan state. The barrel girth, chest girth, shoulder height and body weight of Maganeen dromedaries are 2.42 m, 2.08 m, 1.92 m and 473 kg, respectively. Coat colour is mostly grey, red, or yellow, with straight, short to medium hair length. The Maganeen dromedaries have a large erect hump in the middle of their back with large udders and teats. During the dry season, some of the dromedary's owners migrate to Southern Kordofan, while others migrate north to Gabel Al-ain. They return to Al-mazroob during the wet season.

Shanbali Dromedary

The Shanbali dromedary is found in North and South Kordofan. This breed is reared by the Shanabela and Awamera tribes, who travel between the two states seasonally. They have an average barrel girth of 2.6 m, chest girth of 2.06 m, height at shoulder 1.91 m and body weight of 506 kg. This breed is known for its heavy weight. The most common coat colours are brown, red, grey or yellow with straight, long hair. The well-developed hump is erect or bent sideways. The owners of these dromedaries migrate to Southern Kordofan state near Kadugli during the dry season and return to Al-mazroob during the wet season.

Malian Dromedary

Malian dromedary is located in North and South Kordofan states, which are its cradle and where it is kept by the Maalia and Maagela tribes. During the dry season, these tribes live in South Kordofan (near Kadugli and Daleng towns) and migrate to North Kordofan (Al-mazroob area) during the wet season. The average barrel girth, chest girth, shoulder height and body weight are 2.29 m, 2.12 m, 2.00 m and 479 kg, respectively, in this breed. The height of the shoulders of this breed is quite high compared to other breeds. The coat colour varies from red to grey to yellow, with straight, long hair. It has a large well-developed hump located in the middle of the back. It has large udders and teats.

Butana Dromedary

The Butana dromedary breed is found in the Butana chains (east of Gezira state). These dromedaries have different names based on the owner's tribe. The Butana breed is reared by the Shukria, Ahameda, Magareba and Bataheen tribes. The live body measurements, average barrel girth, chest girth, height at shoulders and live body weight of the Butana dromedary are 2.40 m, 1.94 m, 1.88 m and 446 kg, respectively. Coat colour is mostly red or grey with short to medium hair length. The medium-sized hump is either erect of bent sideways or located in the middle of the back. In the dry season (November to June), the Butana dromedary is found near Tambool town and in the Al-soubag area during the wet season.

9.1.3.15 Libya Dromedary Population

According to Abdalmulaa et al. (2019), three different breeds, Fakhreya, Sirtaweya and Mahari, exist in Libya (Abdalmulaa et al. 2019).

The Sirtawi (Sirtaweya) breed is found mainly in the Sirt area in the middle coastal zone in Libya. The coat colours in this breed vary from light to dark brown. This breed has a medium size with a poorly developed hump and a fairly developed udder. Selected females in some private farms under intensive feeding conditions produce about 3000–4000 kg of milk over a period of 305 days (Wardeh 2004).

The Fakhreya dromedary breed is well known for dairy production (3500 kg/year) under natural grazing conditions in the southern and western areas of Benghazi in Libya (Wardeh 2004).

The OuladBouSayf, Orfella and Fezzan types are variants of the Mehari and its crosses that are found in the western Libyan Oases. They are medium in size, with coat colours close to light, and mainly used for riding, packing purposes and dairy production.

The Tibisti breed is found in southern areas of Libya and northern Chad. They are small riding dromedaries suitable for stony deserts (Wardeh 2004).

9.1.3.16 Tunisia Dromedary Population

Nabul

This Nabul dromedary breed is found in Nabul area at the coastal zone Northern Tunisia and are heavier than the other coastal dromedaries and have larger humps (Wardeh 2004).

Al-Qerawan

Al-Qerawan breed is found in the middle of Tunisia, in the Qerawan district. Its size is of average body conformation, well-built, with a developed hump and muscles, and it is prone to fattening. This dromedary has been extensively trained to perform draft work in agriculture and transportation (Wardeh 2004). According to tribal affiliation (Fig. 9.10), Chniter et al. (2013) identified five groups of Maghrebi dromedaries in southern Tunisia (Chniter et al. 2013): the Gueoudi at Ouled Gharib tribe from Kébili, the Guiloufi in the Beni Guilouf tribe from Kébili, the Merzougui in the Marazigues tribe from Kébili, the Ourdhaoui Tataouine in Oudarna tribe and the Ourdhaoui Médenine in the Tawazins tribe (Chniter et al. 2013). Nine body measurements (body length, neck length, thoracic girth, abdominal circumference, height at the hump, height at the withers, width between shoulders, length of the anterior limb and length of the tool) were taken from a total of 304 female dromedaries (aged 6 years) to identify these groups. The height at the hump and the height at the withers, the thoracic girth and the abdominal circumference, and the body length and the neck length all showed a positive correlation. The tail length, on the other hand, had a negative relationship with the abdominal circumference and height at the withers.

When compared to the Ourdhaoui Médenine dromedary group, the Gueoudi, Guiloufi and Merzougui dromedary groups had longer bodies and larger abdominal circumferences. In comparison to Ourdhaoui Médenine, the Guiloufi, Merzougui and Ourdhaoui Tataouine dromedary groups had the highest thoracic girth and height at the withers. In comparison to the Gueoudi, Guiloufi and Merzougui dromedary groups, the Ourdhaoui Tataouine and Ourdhaoui Médenine dromedary groups had the longest tails. The five groups were clustered together, allowing three main classes of Maghrebi dromedaries to be described: large, medium and small. Six vernacular names were identified based on coat colour (Fig. 9.11): Chagra, Chaâla, Safra, Hajla, Hamra and Zarga. The quality of the hair was mostly rough and thick, that way the female dromedary was named Nagga Chalfi. One small proportion was attributed to the females who had sleek and heavy hair, which was named Nagga Khawar (Fig. 9.12).

9.1.3.17 Morocco Dromedary Population

Dromedary classification in Morocco is mainly based on morphological characteristics (Fig. 9.13), but they are poorly differentiated based on genetic analyses (Piro et al. 2020). Three populations were thus differentiated on this basis in the southern region, and they are the Marmouri, Khouari, Guerzni and Harcha. A multivariate analysis based on morphological measurements found that the Guerzni and Marmouri populations were similar and slightly different from the Khouari population (Boujenane et al. 2019). There is almost no information available on Moroccan dromedary populations. However, some surveys conducted in the south of the country indicate that the Marmouri population is appreciated by keepers for its suitable dairy yield, while the Guerzni population is preferred for its meat production.

9.1.3.18 Other Countries

The Al-Jandaweel (Gandoil) dromedary found in Senegal is similar to the breed of the same name in Mauritania described earlier. The dromedary population in Burkina Faso is similar to that found in Mali. The population found in Namibia is believed to have been introduced by the British Army and is not a natural population of this region. A few herds of dromedaries exist in Botswana, South Africa and the Canary Islands, where they are generally used for touristic activities.

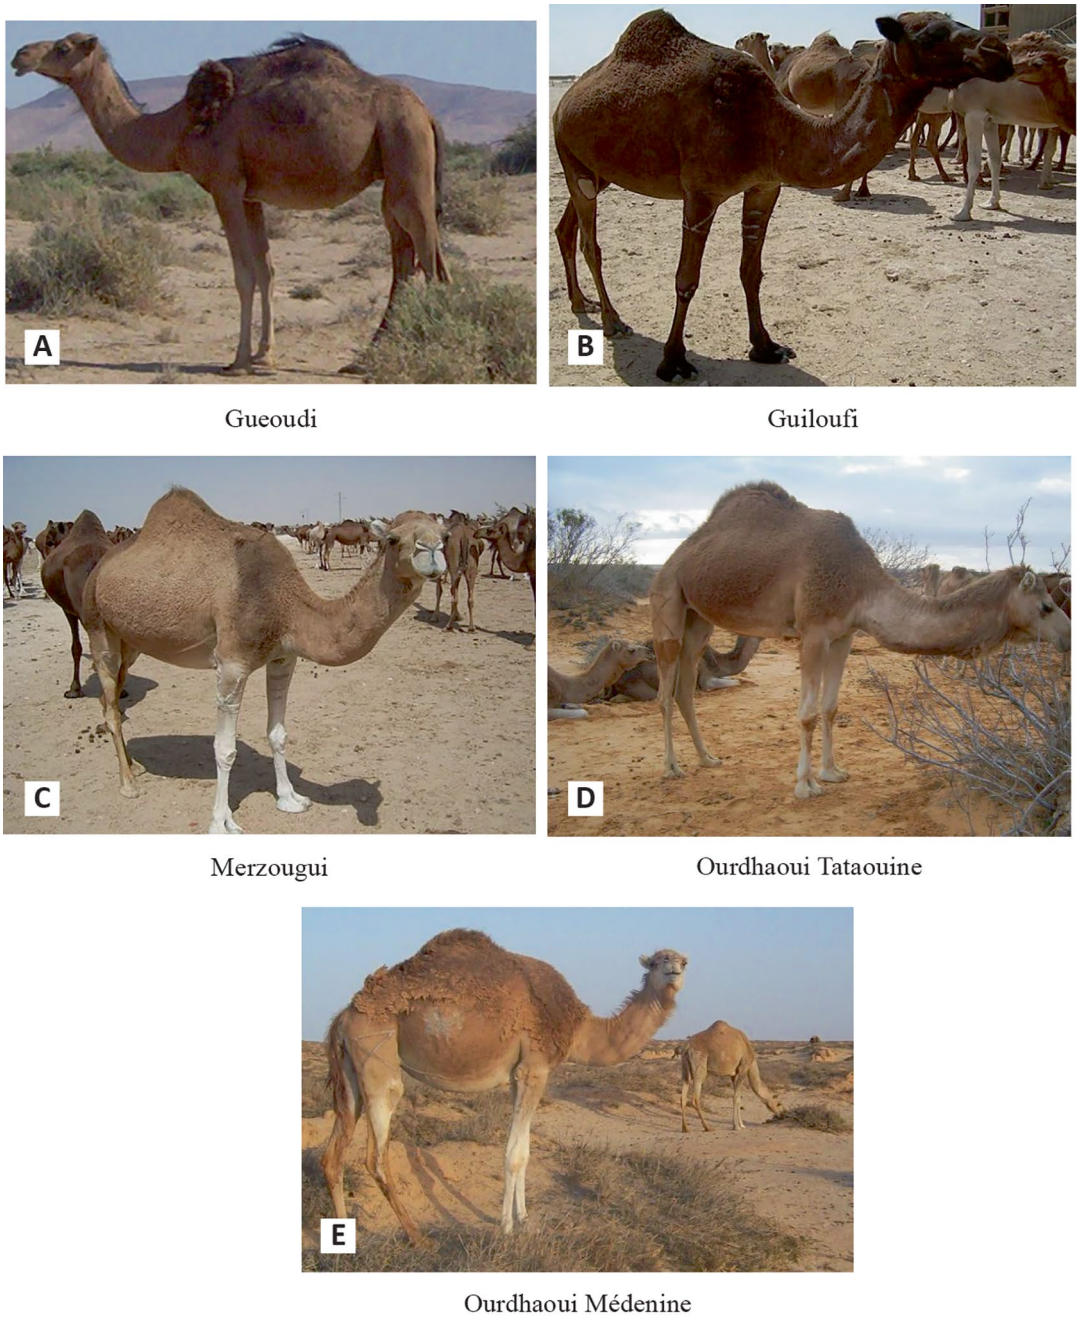

Fig. 9.10 Maghrebi dromedary ecotypes in southern Tunisia according to their tribal affiliation. (From Chniter et al. 2013, licensed under CC-BY 4.0)

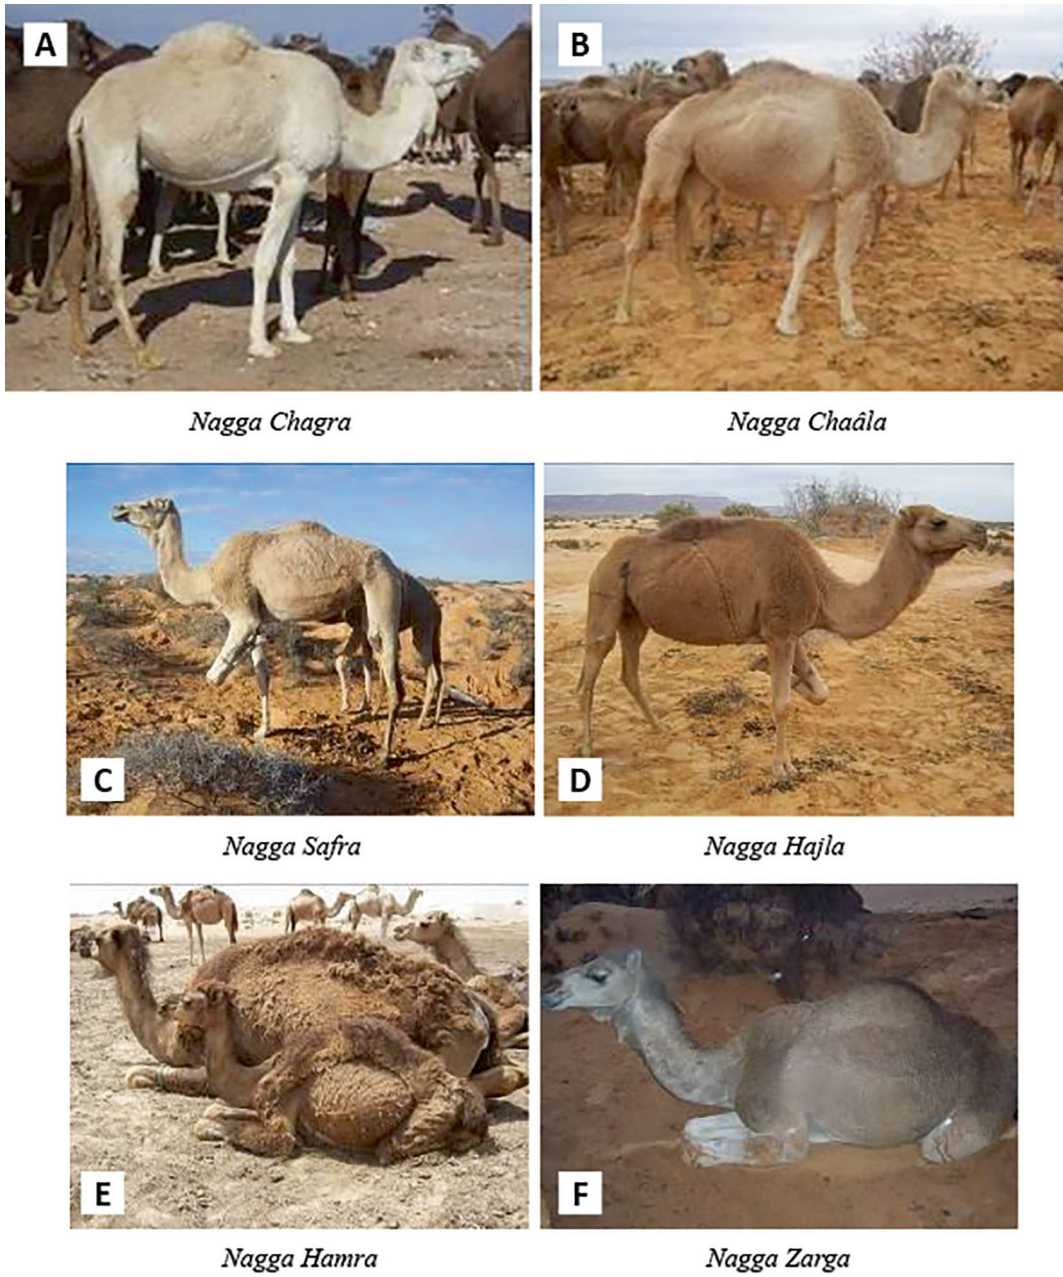

Fig. 9.11 Dromedary coat colours nomenclature used by Tunisian dromedary herders. (From Chniter et al. 2013, licensed under CC-BY 4.0)

9.1.4 Introduced Dromedary Populations

An example of the dromedary breed introduction can be found in Kenya and Namibia. In Kenya, pure Pakistan dromedary exists and their crosses with Somali or Turkana breeds have since spread to the Samburu, East Pokot, Kajiado, Northern Tanzania, Mandera and Marsabit districts (Kuria and Walaga 2008).

Under ranch conditions, the Pakistani breed produces 4–7 litres of milk daily, making it one

Fig. 9.12 Female dromedary of Chalfi and Kawa types. (From Chniter et al. 2013, licensed under CC-BY 4.0)

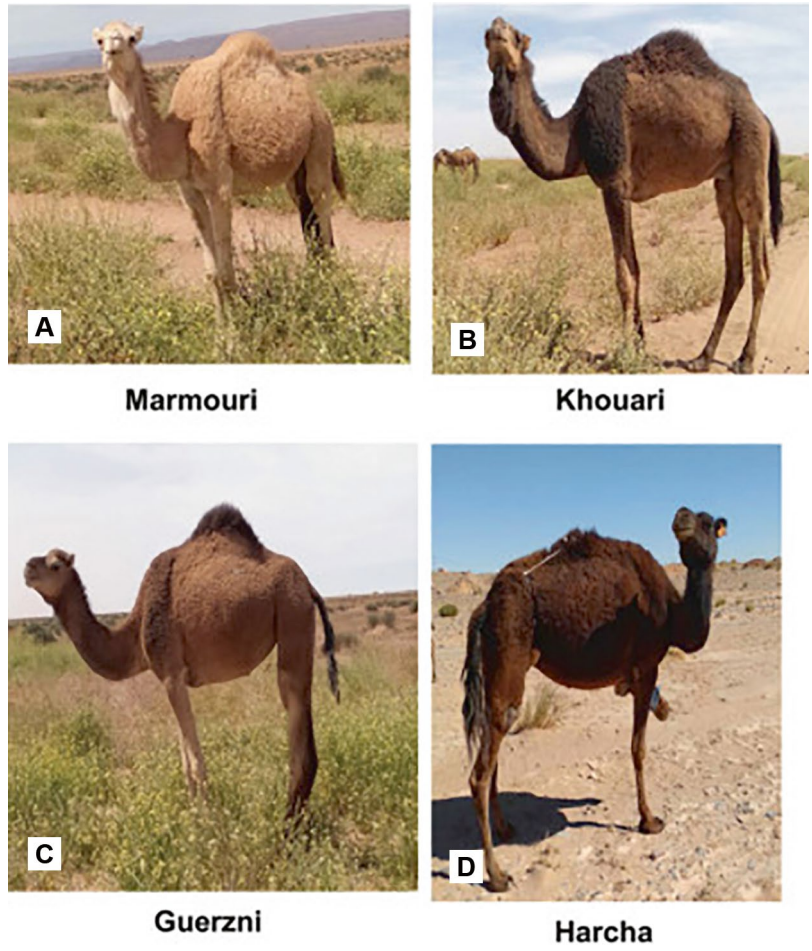

Fig. 9.13 Moroccan dromedary breeds. (From FAOSTAT 2019, licensed under CC-BY 4.0)

of the best animals for dromedary milk production. The coat is mostly of chocolate colour (Fig. 9.14). Mature body weight ranges from 400 to 700 kg, with a drooping lower lip. The first calving occurs between 4 and 5 years. The average standing height is 1.9 m. This breed is a heavy feeder, insufficiently tested on rough terrain and less hardy (Kuria and Walaga 2008).

Fig. 9.14 Pakistani dromedary. (Photo by: Dr. Asim Faras)

9.2 Structures and Organisation of the Dromedary Sector in Africa

9.2.1 Infrastructure and Support Structures for the Dromedary Industry in Africa

Veterinary Services

Veterinary services for dromedaries are provided by both the government and the private sector. Generally, the central government veterinary services under the Ministry of Agriculture (or Livestock) and the Chief Veterinary Officer are responsible for policies, regulations, guidelines, food safety and oversight of public bodies. The provincial (or regional or county) veterinary services under local or regional governments are responsible for preventive animal disease control. The requirements on the health status of the dromedary depend on the World Organization for Animal Health (WOAH) recommendations for a number of animal diseases in the respective regions. So, the strategic objectives could differ from one country to another. For example, in Algeria, the fight against brucellosis is based on testing and slaughtering programmes. However, obtaining freedom from disease status from WOAH is a serious challenge for several African countries surrounded by neighbours where many animal diseases, such as foot-and-mouth disease, brucellosis, tuberculosis, etc., persist, given the frequent, albeit unofficial, inter-country trading of animals and livestock products and movement of animals for grazing across boundaries.

Breeding Services

Breeding services are intended for the selection of genetically superior animals and control of the reproductive process to increase the presence of genes from these superior animals in the overall population (see Chap. 15 for specific breeding goals and alludes to species-specific breeding goals). However, no African country has been able to develop this kind of service for the improvement of the dromedary species. Dromedaries could then be considered neglected in this aspect.

Research Institutions

There are research centres in different African countries interested in research on the dromedaries' species. These include the 'Desert Research Center' in Egypt, the 'Institute of Arid Regions' in Tunisia, the 'Arid Regions Research Centre' and the 'National Institute for Agronomic Research' in Algeria, 'Agricultural and Livestock Research' and the International Livestock Research Institute (ILRI) in Kenya, the 'Institute of Development Research' in Ethiopia and then the 'Institute for Agricultural Research' in Senegal. The universities and other higher education institutions in veterinary and animal sciences also participate in research on dromedaries (for example, the University of Tlemcen and the agricultural school in Ouargla in Algeria and the

University of Ain Shams in Egypt). These research centres contribute to a better knowledge of local dromedary populations; they also participate in the development of local breed conservation techniques or activities and the improvement of their productivity. Globally, there is the NRCC (National Research Camel Center) in India, the Camel Research Center in Inner Mongolia (China), and several public and private centres in the Gulf countries (such as the camel breeding centre in Dubai or the Royal Dromedary Corps in Oman), especially in Saudi universities.

In terms of organisations, there is the International Society for Camelid Research and Development (ISOCARD), a federation of scientific researchers on camelids (camellodists) and scientific and professional associations in the field. The objectives of these Societies are centred on camelids: give an international scientific status to the camelids' sciences, promote the science and practice of camelids, promote the contributions of camelid scientists to the development of camelids' breeding, promote scientific publications in the field of camelids, set high standards of education and training on camelids, promote standards of health and well-being among camelids, organise the International Camelids Conference every 3 years, encourage the exchange of information on the interest of camelids between the members and the various networks and organisations involved, and finally establish and maintain relations with other organisations. The International Camel Organization (ICO) is a non-profit organisation founded by Sheikh Fahd Bin Falah Bin Hathlin, based in Riyadh, on 21st March 2019. Many African countries are currently among the 105 Member States from the six continents of the world. The organisation aims at developing and serving for the recognition of all dromedary-related legacies.

Many national associations or organisations are interested in keeping and the use of dromedaries. In Algeria, there is the National Office for the Development of Equine and Camel Breeding (ONDEC) and the association, the National Interprofessional Council of Camel Breeding. In Sudan, there is the Sudan Dromedary Association (SUCA) and in Kenya, the Kenya Dromedary Association. This kind of association and federation can be found in many countries in Asia and Europe. Examples include the Dromedary Club (Saudi Arabia), Wild Dromedary Protection Foundation in Magnolia, Dromedary Association of Pakistan, French Federation of the Breeders of Camelids and the equivalent European Federation of the camelids. Collaboration between the African, Asian, European and Australian authorities, institutions and organisations could promote policy and strategy development processes for the development of dromedary genetic resources and their utilisation.

9.2.2 Regulation and Legal Bases of the Dromedary Industry

The regulatory instruments that govern the dromedary's keeping conditions, welfare and health are generally the same as those that govern all farmed animals. The texts are more or less country-specific, but they all follow FAO and WOAH recommendations. For instance, FAO published a report in 2011 based on a national consultation on the analysis of constraints affecting the Mauritanian dromedary value chain, with a focus on animal and zoonotic diseases (FAO 2011). This report identified four main types of constraints to the development of the Mauritanian dromedary sector: lack of support for the sector's development, lack of data and knowledge about dromedaries, lack of infrastructure and animal health facilities. Regulatory short comings are highlighted in particular for genetic resource preservation, strengthening the application of the pastoral code, improving epidemiological surveillance of dromedary diseases, the appropriate use of veterinary products, the safety of dromedary food and the processing and marketing facilities of dromedary products (an analysis of broader policy, strategies and action plans for animal genetic resources (AnGR) in Africa including dromedary camels are provided in Chap. 30).

A priority is to improve on local regulations concerning dromedary keeping, its welfare and

the uniqueness of its production. For a better monitoring process, there is a need to extend and harmonise this regulation to the entire sector.

9.3 Structure and System of Dromedary Husbandry in Africa

9.3.1 Geographical Distribution of Farms and Numbers of Dromedary Populations

A detailed review of the world camelid population was recently undertaken by Faye (2020) (Faye et al. 2000). The review showed that dromedary herds have been officially declared in 46 countries worldwide. There are 19 African countries (Table 9.1), 25 Asian countries and 1 European country among them (Ukraine). Dromedaries are only found in Africa, the Near and Middle East, and South Asia, while Bactrians are only found in Central Asia. Kazakhstan is among the few countries where the two species are found. It should be kept in mind that the former Soviet Union included all of Central Asia and that former Ethiopia included Eritrea, and therefore these national entities only represented 38 countries in 1961. Namibia is a relatively new dromedary country, having emerged only in the 2000s. Due to a lack of readily available livestock census, 70% of the data from African countries and 42% of the data from Asian countries are based on estimates. According to the most recent data available in 2022, there were 41,772,353 registered camels worldwide (FAOSTAT 2022). In Africa, there were 34,269,954 with an annual increase rate of about 2.56% (see Chap. 1: African livestock production systems: The past, present and the projected future). However, the population of dromedaries in Africa is not evenly distributed; 14,018,423 heads are in Eastern Africa, 9,401,892 in Central Africa, 5,852,123 in Northern Africa, 4,997,422 in Western Africa and about 94 in Southern Africa. Around 60% of the world's dromedary population is in the Horn of Africa's countries (Somalia, Sudan, Ethiopia, Kenya and Djibouti) (FAOSTAT 2019).

Somalia and Chad alone hold 47.5% (7,243,792 heads) of the dromedaries' population of the African continent (FAOSTAT 2019) and they are part of only eight countries on the African continent with a dromedary population of over one million heads. The other countries include Sudan, Kenya, Niger, Mauritania, Ethiopia and Mali (FAOSTAT 2019). The dromedary population is probably underestimated, especially in the Shelia countries (Mauritania, Mali, Niger, Chad, Sudan and Ethiopia), where the number of heads has been readjusted after exhaustive censuses. For example, in Chad, the number of heads has increased from 800,000 to 1.3 million in a few short years (Faye et al. 2013). In 1961, the date of the first data available, 60% of the 38 national entities reported official data. The total dromedary population at that time was estimated at 12,926,638 heads. The annual growth of the world dromedary population is estimated at 3.07%, but with contrasting national rates varying between −1.95% (Kyrgyzstan, calculated from independence in 1992) and + 45.3% (Oman, calculated from 1961). Overall, 35% of national entities recorded a negative growth rate. An average growth of

Table 9.1 Number of dromedaries in different African countries (FAOSTAT 2019)

Rang	Country	Heads
1	Chad	8,276,416
2	Somalia	7,243,792
3	Sudan	4,895,000
4	Kenya	4,721,900
5	Niger	1,834,943
6	Mauritania	1,500,973
7	Ethiopia	1,281,468
8	Mali	1,241,093
9	Algeria	416,519
10	Eritrea	388,152
11	Nigeria	289,794
12	Tunisia	237,516
13	Egypt	119,885
14	Djibouti	70,894
15	Libya	66,667
16	Morocco	60,808
17	Burkina Faso	20,345
18	Senegal	5030
19	Namibia	93

more than 10–15% cannot be maintained without the importation of live animals because the natural growth of a camel herd can be estimated at about 5–10% (Bonnet 1996; Adamou 2008). In general, the evolution of the dromedary population of the African continent is constant between 1961 and 2019. Thus, the dromedary population multiplied by 1.57 between 1961 and 1980, by 1.33 between 1980 and 2000 and by 1.80 between 2000 and 2019 (FAOSTAT 2019). According to Faye et al. (2013), some African countries are experiencing rapid growth during the recent years such as Algeria, Chad, Mali, Mauritania, Ethiopia and Eritrea, while some have been experiencing steady growth since 1961, such as Burkina Faso, Djibouti, Egypt, Kenya, Niger, Nigeria, Pakistan, Somalia, Sudan, Tunisia and the Western Sahara. Others have stable dromedary numbers, such as Libya and Senegal, and those with a very large decline in dromedary numbers, such as Morocco.

The Algerian dromedary population increased from 286,670 heads in 2007 to 416,519 heads in 2019 (FAOSTAT 2019). This increases the results from several dromedary development programmes established by the Algerian state. In fact, the dromedary livestock industry experienced a considerable boom from the year 2000, following the introduction of the birth premium, which is a kind of financial incentive granted to farmers for any birth of a new dromedary by the Ministry of Agriculture (Bedda et al. 2019).

Over the past 50 years, camelids have grown rapidly, after goats and buffaloes, as shown in Table 9.2. Besides the various data gaps of camelids increased from 16,494,169 in 1969 to 37,509,691 heads in 2019.

Table 9.2 Evolution of African livestock animal numbers between 1969 and 2019 (FAOSTAT 2019)

	2019	1969
Camelids	37,509,691	16,494,169
Donkeys	50,583,572	38,342,749
Horses	59,041,725	60,100,684
Buffalo	204,342,419	106,224,223
Goats	1,094,068,295	377,651,477
Sheep	1,238,719,591	1,080,656,610
Cattle	1,511,021,075	1,069,858,656

9.3.2 Dromedary Breeding Systems in Africa

Like in all domestic species, breeding activities rely on the capacity to record and manage data. Dromedaries are not really on major livestock mainstreams, giving very narrow room for comprehensive breeding schemes. Nevertheless, based on available information, breeding strategies are selection and cross-breeding and very rarely interspecific crossing. Mating systems are controlled for small herds and random when numerous herds meet during nomadic movements.

9.3.2.1 Selection

Selection pressure on the dromedary is low. Apart from keeping animals for a specific purpose (conditioning, riding, milking), few programmes based on selection according to the performance of their offspring have been developed, with the exception of race animals.

Traditional dromedary breeding systems are extensive, based on the use of natural resources and herd mobility. The biological peculiarity of the dromedary is its very low fecundity. Age at sexual maturity is about 3 years, gestation length is long (13 months), and calving interval is generally about 2 years. In addition, calf mortality is high (could reach 20% and even more), hence the reproductive rate is low, though the longevity of the dromedary could compensate for it. Despite these limitations, there is potential for significant productivity gains through selection and breeding, hence scope for the improvement of dromedary meat and dairy productivity in intensified production systems (Breulmann et al. 2007).

Generally, the intensity of selection for females is low, based mostly on reproduction, mothering ability and conformation. This is because almost all breeding females are required for the maintenance and growth of the herd. Conversely, a high selection intensity can be placed on the males. Once a male has been selected, it can be used continuously for 2–12 years, with an average of 7 years. The ideal age for sexual activity for a male when it can be used for breeding is between 6 and 12 years old.

At younger ages, the weakening of the rut does not allow it to mate efficiently, while at older ages, its fertility declines and the male becomes more selective; thus, some females become abandoned without a mate. However, females remain well fertile over 25 years old and can produce 7–9 calves in their lifetime. Most breeders, however, start by eliminating the least fertile females at the age of 15. The breeding objectives include many aspects other than commercial meat and dairy production. They can include aesthetic preferences (coat colour and colour pattern) and behavioural aspects, such as good maternal instinct, ability to live in herds and ability to travel long distances (Doutresoulle 1947; Chaibou 2005; Djomtchaigue et al. 2015). The dromedary's ability to withstand extreme weather conditions (drought, etc.), coating is another important advantage that affects high productivity. Breeders practice phenotypic selection to identify the best, mostly among male candidates. The selection of breeding males is based on available information on their parents (family selection) and themselves (individual selection). A farmer's survey on criteria for the choice of the future sire indicated that male selection is based on information from its dam. The features considered include the genetic type, size of the body and hump, milk yield, health status, disease resistance and drought tolerance. Some criteria also considered include fertility, duration of lactation, offspring quality and coat colour. In selecting a male, breeders also take into account certain qualities of the sire, such as genetic type, the large size with a large bump (conformation), the quality of its progeny and health status with disease resistance, tolerance to drought and fertility. The individual characters considered in the selection of candidates include large size, conformation, beauty (slender appearance and fine hair), docility (young dromedaries that show early aggression are often removed), disease resistance, drought tolerance and coat colour (Cherifi et al. 2017).

The development of modern mini-dairy, particularly in Mauritania and Algeria, is currently helping to direct selection towards the most milk-producing animals. The creation of interprofessional organisations and breeders' associations is amplifying this trend (Gherissi and Gaouar 2022a).

9.3.2.2 Cross-Breeding

This breeding strategy, which consists of mixing at least two distinct gene pools, has been described by Doutresoulle (1947). It was a strategy used to upgrade or create genotypes destined for racing or disease resistance during the colonial era in French-speaking West Africa.

9.3.2.3 Interspecific Crossing

Hybridisation between *C. dromedarius* and *C. bactrianus* was thought to be impossible for centuries. However, a lot of the research on cross-breeding between the dromedary and Bactrian varieties has been undertaken in the former Soviet Union, particularly in Kazakhstan. Such hybrids have long been known in Turkey, northern Iran and Afghanistan (Khan et al. 2003). Planned hybridisation was very important in Turkey in the second decade of the last century, when up to 8000 female dromedaries were imported from Syria and further south to be mounted by Bactrian males. F1 male hybrids with normal spermatogenesis are almost always fertile. When bred with males of either species, the hybrid female produces offspring that look like the male parents (dromedary or Bactrian). In terms of size, hardiness, endurance and longevity, the F1 is heterogeneous with a longer single hump that is less developed than in the dromedary. Some Bactrian characteristics, such as the beard and hairy legs, are preserved (Khan et al. 2003).

The dromedary crosses with the Bactrian to produce a strong draught animal with a wool yield similar to the Bactrian. The hybrid's dairy production and milk fat content are midway between the yields of the two parental types. Other crosses, particularly those resulting from F1 hybrids, appear to produce weak, poorly conformed animals that are difficult to maintain. (Khan et al. 2003) successfully crossed the camel and the llama in Dubai (Khan et al. 2003). 'Camella' was the name given to the offspring (López 2010).

9.3.3 Dromedary Production Systems in Africa

9.3.3.1 Nomadic System

Nomadic pastoralists do not have permanent fixed habitats and the whole family follows the movements of the herd, sometimes over long distances (hundreds of kilometres) (Chergui et al. 2023). They move at the head of the herd, of which they are not always owners but guardians. They lead a seemingly unstable existence: they move constantly, and the movements are traditionally done on donkeys. Dromedaries move from one water point to another, using rivers, streams and wells. As a result of this mobility, nomads practice little or no agricultural activity (Cherifi et al. 2013).

H'mil (Free Range)

In the great Sahara region, where great distances allow families to isolate themselves in the vastness, dromedaries are often left with complete freedom (Chergui et al. 2023). They know the well where they can find the shepherd who provides water, and so they return quite often when they are thirsty (Radfar and Aminzadeh Gowhari 2013; Habte et al. 2021; Chergui et al. 2023). This system is practised mainly in poor seasonal conditions (e.g. no rainfall, etc.) where dromedaries are left to freely search for water and pasture. The disadvantage is that products of the dromedary, such as milk, hair, etc., cannot be exploited during this period, and there is also a high risk of disease spread within the herds, an increase in mortality rate due to road accidents and loss of dromedary calves that are not marked. This system also results in difficulties with dress coating (Gauthier-Pilters 1977). It is a free-range extensive production system practised mostly when the year is presumed unfavourable due to harsh weather, and hence a lack of pasture. It is a system characterised by movements towards water points and the search for pasture that thrives with little rain. The majority of breeders who practice this system are sedentary, giving themselves to various activities, including trade, throughout the year. The control and recovery of dromedaries is done near water points in the summer season (Bensemaoune et al. 2018; Chergui et al. 2023).

9.3.3.2 Sedentary System

'Sedentarisation' is sometimes used to describe a process of evolution and adaptation of nomadic populations which reduce the amplitude of their movements and include agricultural practices in their activities (Kaufmann 1998; Chergui et al. 2023). The sedentary production system is characterised by movement of herds over long distances during the day, with return to the village at evening (Bourbouze 2006). Currently, in Africa, very few sedentary herds exist (Chergui et al. 2023). The few that do exist are found in peri-urban regions, and most of them have a dairy vocation (Gherissi and Gaouar 2022b).

9.4 Dromedary Production Objectives

Dromedary rearing has long been a vital part of the social and economic lives of people living in arid and desert areas of Africa and Asia. Dromedaries are multifunctional animals used in African pastoral production systems to provide milk, meat, blood, hides and skins, transportation, barter trade (sale and exchange) and social and cultural functions (Kuria and Walaga 2008). The image of the dromedary is a symbol of mankind's survival in the desert, and it is associated with the history of the great nomadic civilisations of dry and hot regions characterised by long periods of unfavourable weather, often exceeding 8 months, and rare and weak precipitations (Ramet 2013). As a result, in recent years, this animal has become the animal of choice for responding to the phenomenon of global warming.

9.4.1 Primary Production Objectives

9.4.1.1 Milk Production

Dromedaries have an outstanding milk production, especially in harsh environments, when

Fig. 9.15 Traditional milk production. (From Cherifi et al. 2013, licensed under CC-BY 4.0)

compared to cattle and small ruminants under similar harsh environments. Their lactation persists well into the dry seasons and rarely ceases even during extended dry periods (Chergui et al. 2024). Generally, the females are milked twice a day, morning and evening, with the presence of the dromedary calf that acts as a stimulus for milk letdown in the udder (Fig. 9.15). Dromedary milk production is difficult to quantify due to the mobility of herders and irregular milking. The frequency of milking varies from once a day to twice a day, depending on the individual breeder (Nega and Tefera 2012; Kebede et al. 2015). The milk is taken mostly for home consumption and sometimes for sale. Daily milk yield ranges from 5 to 10 litres, depending on breed and production system. For one of the most famous Algerian dairy camel, the Sharaoui camel breed, Chergui et al. (2024) reported the following lactation performances: an average daily milk (DMY), fat (DFY) and protein (DPY) yield were 6.77 ± 0.82 kg/day, 4.15 ± 0.91% and 4.49 ± 0.20%, respectively (Chergui et al. 2024). The mean of total milk yield (TMY) was 2696.39 ± 343.86 kg during a mean lactation length (LL) of 398.38 ± 20.65 days. There is no significant difference between intensive and semi-intensive breeding systems for TMY, DMY and LL. However, the total amount of fat was significantly higher in the intensive system, and the DPY content was significantly higher in the semi-intensive system (Chergui et al. 2024).

The development of peri-urban farms around could constitute the core of dromedary dairy farming in the future. The use of dromedary in dairy production is becoming more rational in Mauritania, Niger and Chad (Chaibou 2005; Djomtchaigue et al. 2015; Faye et al. 2000). It is expected that dromedary milk production, which was previously practised mainly for the survival of indigenous peoples in arid regions, will grow with the application of technologies to become a key alternative source of milk and dairy products for the general population. In this regard, commercial dromedary milk is to be increased (Fig. 9.15) (Cherifi et al. 2013).

In some pastoralist tribes, such as the Afar and Somali, women are not allowed to milk dromedaries because they believe lactating dromedaries do not let down enough milk for women (Kebede et al. 2015; Seifu 2009; Simenew et al. 2013). However, amongst the Rashaida tribe, dromedary milking is practised by women. This is also the case in Kenya, Somalia and most parts of Sudan (Eisa and Mustafa 2011). Smoking the milking vessels with local herbs is thought to enhance the flavour, taste and quality of the milk while also extending its shelf life (Seifu 2009; Wanjala et al. 2016; Gebremichael et al. 2019). Smoking milk-handling containers inhibited microbial growth and could be used for sanitation and preservation

of raw dromedary milk in arid and semi-arid areas where cold chain facilities for milk preservation are unavailable (Gebremichael et al. 2019). The estimated average daily milk yield per dromedary in Ethiopia under pastoralist milking practices ranged from 2 to 6 litres, according to (Gebremichael et al. 2019). The Algerian dromedary's female can produce 3.96 ± 1.24 litres of milk per day on average. Bakheit et al. (2008) conducted a comparative study of dromedary milk production in Sudanese traditional and semi-intensive dromedary farms, finding that the average daily milk yield for the semi-intensive and traditional systems, respectively, was 6.85 ± 1.32 and 3.14 ± 0.66 liters (Bakheit et al. 2008). AM et al. (2018) found a similar result in Egyptian dromedary herds, finding that daily or total milk yield was significantly (P = 0.001) higher for dromedaries under improved farming systems than for those under traditional pastoral systems (26.12 vs 13.41 litres of milk, respectively). With improved feed, water and husbandry, lactating dromedaries can yield up to 20 litres per day (Kuria and Walaga 2008).

Benefits of Dromedary Milk

The dromedary milk has a high nutritional value, often discussed in medical literature. It is slightly saltier than cows' milk, three times as rich in Vitamin C and is known to be rich in iron, unsaturated fatty acids and Vitamin B. Surveyed farmers believe it is suitable for treating diseases such as diabetes and liver problems. It may play a role in reducing coronary heart disease, and some recommend it to HIV/AIDS patients. Research is beginning to demonstrate the scientific basis for these properties (Cherifi et al. 2013). Dromedary's milk is thus preferred over other livestock species' milk because of its taste, nutritive value, and health properties, and it is perceived that dromedary milk prevents thirst even when walking long distances. It is a natural and essential food item in areas where there is water scarcity.

By virtue of its nutritional qualities, dromedary's milk constitutes the essential basis of the diet of nomads, as well as a remedy against many ailments (Viateau 1998). While the virtues of dromedary milk have been prophesied over 14 centuries ago, scientists are only now just beginning to test prophetic medicine, widely brought up to date by the Sahrawi, Tuareg and Berbers. The value of dromedary milk has been confirmed or is in the process of being confirmed by modern science. Scientists are also beginning to discover the preventive and curative medicinal properties of dromedary milk and its value in the treatment of many diseases. It is believed that it contains antibiotics of a very rare type and substances that can fight diseases that modern medicine cannot yet cure (Konuspayeva et al. 2004).

The therapeutic benefits of dromedary milk are numerous, with diverse roles in autoimmune diseases, metabolic disorders, tuberculosis, hepatitis, cancer, rickets, diabetes, Crohn's disease, cirrhosis, autism and rotavirus diarrhea (Zibaee 2015). Previous research on the Arabian dromedary (*Camelus dromedarius*) revealed that its milk has beneficial effects in a variety of human diseases, including significant hypoglycaemic activity. The cellular and molecular mechanisms underlying such effects, however, are unknown. As a result, Abdulrahman et al. (2016) theorised that dromedary milk might act on the human insulin receptor (hIR) and related intracellular signalling pathways (Abdulrahman et al. 2016). Using bioluminescence resonance energy transfer (BRET) technology, they investigated the effect of dromedary milk on the activation of hIR transiently expressed in human embryonic kidney 293 (HEK293) cells. BRET was used to examine the physical interaction between hIR and insulin receptor signalling proteins (IRS1) and growth factor receptor-bound protein 2 in live cells and in real time (Grb2). In the absence of insulin stimulation, dromedary milk did not result in an increase in the BRET signal between hIR and IRS1 or Grb2. It did, however, potentiate the maximal insulin-promoted BRET signal between hIR and Grb2, but not between IRS1 and Grb2. Dromedary milk appears to have a differential impact on downstream signalling because it significantly activated ERK1/2 and potentiated insulin-induced ERK1/2 activation but not Akt activation. The peptide/protein nature of the active component in dromedary milk is suggested by preliminary fractionation. For the first time,

this study shows that dromedary milk has an allosteric effect on insulin receptor conformation and activation, with different effects on intracellular signalling. These findings should contribute to a better understanding of the hypoglycaemic activity of dromedary milk with potential therapeutic applications.

9.4.1.2 Meat Production

Meat is a preferred source of animal proteins because of its richness in amino acids (Geay et al. 2002). The dromedary has a high carcass yield and meat with dietary qualities that are appreciated and consumed on a large scale in the Algerian Sahara (Faye et al. 2013; Ould El Hadj et al. 2002). It is for this reason that dromedaries, adapted to the extensive conditions of the arid zones, are increasingly involved in intensive production systems (Faye and Porphyre 2011; Ould El Hadj et al. 2002; Salter 2013; Smith et al. 2013).

The contribution of camelids to the world production of red meat is very marginal due to the size of the camels' population: it represents 0.13% of the meat produced in the world and 0.45% of red meat. However, because a high proportion of camels are confined to arid countries, their contribution to meat production appears to be higher locally. In East Africa, dromedary meat represents 4.1% of red meat produced, 4.8% in North Africa, 2.9% in West Africa, and 3.7% in the Near East. Everywhere else, it represents less than 1% of total red meat. In Northern Africa, the total production of dromedary meat increased between 1961 and 2011, from 21,600 to 63,143 tonnes, i.e. three times in 50 years, and therefore in proportions not commensurate with the increase in milk production (Faye et al. 2014). While the dromedary population of North Africa represents only 3.5% of the world's dromedary population, dromedary meat production is equivalent to 15.4% of world's dromedary meat production. Dromedary meat represents 4.8% of red meat produced in North Africa, but it varies between 1.1% in Morocco (66.9% in the Saharan provinces), 1.2% in Tunisia, 1.3% in Algeria, 4.6% in Egypt and 9% in Libya (Faye et al. 2014). This shows the place of this product in the Maghreb countries. Dromedary meat is widely consumed in certain regions of Africa, such as Somalia, Mauritania and Western Sahara. Per capita rate of consumption is 0.14 kg/year in Algeria, accounting for 4.2% of the total red meat consumed (Faye et al. 2014). The growth observed in dromedary meat consumption is linked to an increase in the slaughter rate in this growing population and to a significant increase in the weight of the carcasses. This is evidenced by the situation in Chad between 1991 and 1996, where production increased from 244,708 tonnes in 1991 to 755,232 tonnes in 1996, an increase of 67.59% in 6 years (Mbaïgaou 1998).

Surveyed breeders confirm that production is primarily driven by the sales of livestock and that meat production is the true purpose and source of income for the farmer in Northern Africa (Fig. 9.16) (Cherifi et al. 2013). Due to the low

Fig. 9.16 Dromedary slaughter and carcass/meat handling. (From Cherifi et al. 2013, licensed under CC-BY 4.0)

reproductive performance of dromedaries compared to cattle and small ruminants, dromedary meat production is less important in the eastern African region. The pastoral communities' main source of meat is small ruminants, but dromedaries are occasionally slaughtered for meat. Pastoralists claim that dromedaries'meat is of higher quality because of its nutritional value and flavour. The majority of dromedaries are slaughtered at home for personal consumption, with any surplus meat sold to a butcher (Kuria and Walaga 2008).

The Virtues of Dromedary Meat

In dromedary keeping, meat is the first source of animal proteins, thanks to its richness in amino acids, it is among the noble proteins (Geay et al. 2002). The dromedary has a high carcass yield and meat with dietary qualities that is appreciated and consumed on a large scale in the Sahara (Faye et al. 2013; Ould El Hadj et al. 2002) and where available. Thus, dromedaries are increasingly included in intensive production systems (Ould El Hadj et al. 2002; Salter 2013; Smith et al. 2013; Faye et al. 2011).

9.4.1.3 Wool Production

The wool 'Oubar' is considered a secondary product of dromedary production. Farmers use the wool for the manufacture of Barnous, tents and dromedary chest caches. Herders are not always aware of the market value of the dromedary wool and its usefulness in the manufacture of handicrafts (carpets, clothing, decorative items, etc.) with great export potential. A cottage industry based on these high-value products will have a high commercial value (Cherifi et al. 2013). In countries where tourism is well-developed, products developed from the dromedary wool and skin could have a significant commercial outcome.

9.4.1.4 Bone and Blood

Dromedaries also provide blood, which is mixed with milk to create a diet component for young children, including the herders (Kuria and Walaga 2008). They also serve for social and cultural purposes, facilitating social transactions such as gifts, loans to relatives and friends and the provision of food during ceremonies. Dromedaries are sold and exchanged only during droughts or when pastoralists require large sums of money for health or school fees. The importance of the dromedary in the Samburu community is explained by these unique and strategic uses of dromedaries and related products. Despite all of the advantages of dromedary production in East Africa's pastoral areas, dromedaries still face challenges in their natural habitat, including diseases, drought and predation, which expose the pastoralists to risks of losing their source of livelihood (Kuria and Walaga 2008).

Dromedary bones were once used as tent poles when wood was scarce (Lasnami 1986). Ibn Khaldoun (1377) reported that during the drought, after prolonged fasting, nomadic inhabitants collect bleached dromedary bones, pulverise them and mix them with water to form a paste for consumption. While the Muslim religion prohibits the use of blood as food, certain nomadic populations of southern Ethiopia and northern Kenya take 5–7 litres of blood, 2 or 3 times a year, from each animal to drink fresh or mixed with milk (Faye and Bengoumi 2002).

9.4.1.5 Other Products

The development of by-products from wool and leather remains below its potential. In recent years, some progress has been achieved through projects aimed at promoting technical innovation in these sectors. For example, dromedary wool was traditionally only used to make burnous-type coats or the winter gown (wazra) of Libyan and southern Tunisian dromedary drivers. However, in this sector, which is largely linked to craft processing, the automatic separation of the type of fibres (separation of jars hair from better-quality fibres) and innovations in finished products for customers seeking more refined dromedary wool fabrics have enabled advances in this sector under the impetus of the procamel project in Tunisia and Egypt. Similarly, the leather and skins sector, long neglected due to the low quality of the product, resulting from poor slaughter procedure (quality of collection), quality of treatment in tannery and skin diseases, is currently undergo-

ing some development in Tunisia and Egypt. This work aims at creating specifications for the collection and technological innovation to obtain finished products of high quality suitable for export markets. In Tunisia, collaboration between the producers and the Technical Centre for Leather and Footwear, which works to find quality products, is promoting the development of this by-product (Faye 2014).

9.4.1.6 Pharmacopoeia Aspects of Dromedary Urine

Almost everything obtained from the dromedary is useful in one way or another. Some keepers claim that they use everything, even the dung and saliva, which is exploited for its baking soda content (Mammeri and Khir 2018).

The traditional pharmacopoeia in many countries uses dromedary urine as a therapeutic ingredient. The consumption of dromedary urine, either alone or mixed with dromedary milk, has been traditionally used for health (Alkhamees and Alsanad 2017). Young nomadic girls and women use the dromedary urine collected as 'champing'. According to the nomads, this strengthens the hair and makes the hair red like using henna (Lasnami 1986). Studies have demonstrated the existence of antimicrobial activity against pathogenic bacteria in urine associated with dromedary milk (Benkerroum et al. 2004) and lactoferrin activity against hepatitis C virus infection and cancer cells (Esmail et al. 2008). Since ancient times, dromedary milk and urine have been used as medicines in certain parts of Asia and Africa. Dromedary milk, alone or in combination with dromedary urine, has been shown to be effective in the treatment of a variety of clinical conditions, including diabetes, cancer, food allergies, autism, viral hepatitis and a variety of other viral, bacterial and parasitic infections, according to significant evidence derived from laboratory and limited clinical studies. Furthermore, a number of potential cardiovascular benefits of dromedary milk and urine, particularly their antiplatelet and fibrinolytic actions, have been demonstrated (Abdel Galil and Alhaider 2016).

9.4.2 Use of the Dromedary in Africa

Among the Tuareg and Saharawi, the dromedary has always been considered a prestigious animal and is exhibited during cultural events. Indeed, the animal partakes in many religious (Enid El Adwa), sporting and customary ceremonies. The dromedary has long been used as a means of transport for pilgrimages in Tuareg and Saharawi and for funeral ceremonies that require the use of the dromedary as a means of transport. The place of dromedaries is central in the culture of the Sahara as a source of wealth, prestige and serves as dowry (at weddings); thus, at weddings, the parents of the bride or groom may gift 2–4 dromedaries to their children. To accompany the new bride to her future husband, a procession is organised on the backs of the most beautiful dromedaries.

The dromedary is also used among the Tuareg as a means of compensation in dispute resolution. It is used as a piece of embellishment, especially for honoured guests, and constitutes a treasure for the tribes where they are regarded as 'friends and companions of road and transhumances of the Sahara'. Thus, among all these ethnic groups, the greatest honour that can be done to a distinguished guest or a relative is to offer him a meal based on meat from the dromedary.

9.4.2.1 Coatage

Coatage refers to all the accessories necessary for an activity that the dromedary will carry out. The coatings for the pack saddle start from the age of 4–5 years, but the full load is assigned to the dromedary only from 6 to 8 years, not to disturb the growth and avoid joint deformations. The career of a 'carrier' dromedary can last 12 years. Coatings for agricultural activities begin at the age of 3 years, when a ring is placed in the nostrils of the animal. Only one man is needed to drive the dromedary when it is well coated. Depending on the husbandry conditions, the productive life of the dromedary at work varies from 6 to 20 years. The coatage for saddle riding starts from the age of 3 years, but only the adult animal,

around 6 years, is actually used (Lhoste et al. 2010).

During the entire coating period, which is a period of stress, animals must be properly fed and watered; an additional 3 kg of bran cereals per day is recommended (Lhoste et al. 2010).

The dromedary coatings includes a basic coat, which lasts from 6 to 8 weeks, during which the animal learns to sit, lie down, move forward and backwards, turn and carry a load on its back. It takes about 2 more weeks to coat wagons at the pull, a little more if a coat is combined with the pulling of agricultural tools. The dromedaries are guided by a rope passed through the nasal ring. They are led to walk and trot with animals accustomed to being loaded, to move with a load and to obey the instructions given through the rope. Straight line walking is acquired quickly (Lhoste et al. 2010).

For a heavy work period, frequent breaks are advised. The length of the ploughing lines can also be limited to about 50 metres to allow the animals to catch their breath at the end of the furrow. Never allow animals to stop during a skate for no apparent reason. It is risky to 'overload' a hitch even once, as animals can become suspicious and reticent (Lhoste et al. 2010).

9.4.2.2 Agricultural Work and Importance of the Dromedary in Breeding

The use of the dromedary in agriculture is traditional both in oases (water exhort) and in agricultural regions of medium mountains (ploughing, sowing), as a single draught animal (Tunisia, Egypt) or paired with a donkey or mule (Morocco). Its coupling to various wagons for the transport of property or people is much less common than in other countries such as India or Pakistan. As a transport animal, it is still the pack which is the most common, for example, for the transport of wood (Algeria) or dates (Tunisia, Morocco) (Faye et al. 2014).

The productivity and integration of the dromedaries into a generally poor, arid environment is remarkable. This coping capacity is quite superior to cattle, especially exotic breeds recently introduced into Africa. The dromedary, nicknamed 'ship of the desert', is an excellent animal for pack and saddle. It is used to till the soil, draw the water from the wells and turn the grain wheels. The dromedary is a great walker and feeds on almost all the plants, herbaceous and woody species in the pasture area. However, it takes small amounts at a time and is considered to be one of the pseudo-ruminants that does the least overgrazing, unlike, for example, goats. When the pasture is used by other animals, it can, thanks to its large size, still find forage where other species could not reach: 70% of the dromedary feed comes from the same thorny shrubs, while 80% of cattle feed comes from grass. It has the ability to graze up to 80 km from a water point and to remain without drinking for several days, if the water content of the plants allows it. This is not the case for cattle. The resistance of dromedaries to climatic rigour is remarkable. During the great droughts of the past years, cattle losses were of the order of 80% in some regions, while the dromedary population suffered only a relatively minute loss, not exceeding 20%. According to a recent study carried out in Sahelian areas, the dromedary herd seems to revolve around a numerically constant nucleus of adults aged 5–12 years old. This partly explains why the dromedary population can recover fairly quickly after high mortality. Adapted physiology of the dromedary to survive in the most arid environments comes from a number of physiological originalities. In addition, unlike other warm-blooded animals, the dromedary does not waste its water reserves during the hot hours of the day to cool down by sweating (Bengoumi and Faye 2002).

In Eritrea, dromedaries are frequently used as pack animals, for riding, for ploughing and for driving oil mills known as Assara. In addition to providing transport during migrations, they are regularly used for carrying fuelwood, trade goods and, most importantly, water for household consumption (Gebrehiwet 2021).

9.4.3 Sociocultural Role of Dromedary Livestock

9.4.3.1 Saddle Dromedary

There is no definition of the ideal physical feature of the dromedary. Generally speaking, the perfect dromedary should be sturdy, heavy, muscular and well-boned. Several factors determine the load to be transported by the saddle dromedary: age, size, breed and distance to travel. The other factors involved are: the terrain, the pace and the forage covering the road. The animal must be educated between 2 and 5 years, and it is only when it reaches its full maturity that it must be required to transport complete loads, proportional to its strength. The load of the animal must be balanced, and the best system is therefore to divide the luggage into two equal parts which are suspended on both sides of the hump.

9.4.3.2 Saddle and Racing Dromedaries

The saddle and racing dromedary is an essential means of communication in remote arid and semi-arid regions of Africa. It enables police patrols, nomadic guards, extension workers and nomadic populations themselves to move. It is likely that this mount role will not be completely abandoned by the pastoral people even in the face of the rampant proliferation of off-road vehicles. The use of saddle dromedaries as war animals probably dates back to 190 BC (Tennews 2015). The ideal saddle dromedary is thin; it has long legs and a strong bone structure. An adult male saddle dromedary must give an impression of male strength, boldness and symmetry. A short head with a high forehead, a buzzed nose and a rather deep knout with firm lips are desirable characteristics. As an example, the dromedary of Targui in Algeria and in the countries of the Sahel is used as a saddle animal, unlike other breeds, which are used for the pack and the production of meat.

Four speeds have been identified to describe the different gaits at which the saddle dromedary moves: the walk, the small trot, the large trot and the amble. Normal walking speed is about 4 km per hour, while the small trot usually allows the animal to move at 8–12 km/hour on flat ground. At the high trot, the speed described for North African and Arab dromedaries is 14–19 km per hour (Sharp 2016). According to Philipponneau (2014), the dromedary can run very fast. In racing, it reaches 70 km/h, which is faster than a horse (Philipponneau 2014).

9.4.3.3 Sociocultural Uses

In cultural ritual ceremonies, the dromedary is used in various ways (pack animal, saddle animal, race animal, etc.). In these cases, the richly adorned animal can be used in the company of many others for demonstrations, parades or even breeding. For example, for the Chadian ethnic group called Kréda, during the first wedding ceremony: 'ossana', for 3 days, the son-in-law and his companions come to camp next to the *Ferrick* (traditional housing in Chad) of the in-laws. They make the turn three times before getting off their steed (dromedary), richly adorned in the middle of *youyous* (cries of joy emitted by the women). Although the dromedary is not directly involved in religious ceremonies, it contributes indirectly by providing the needs of the cameleers. They can sell one or more dromedaries to meet their food needs during the Ramadan period (sacred fasting), dress the family for religious holidays, or buy very good rams for the feast of Eid al-Adha. They are sometimes sacrificed on the occasion of this feast in place of the sheep.

In marriages of some Berber tribes in the south of Tunisia, as in the society Touareg or Afar, the dromedary is used to pay the dowry (Morin 2006; Cabalion 2013). Among the Fili, the dowry is higher, and if the marriage is endogamous (between clan members), 10–30 sheep, a dromedary and money are required for the dowry. However, if the marriage is exogamous, i.e. outside the clan, the dowry can exceed 40 sheep (in addition to the dromedary and money) (Waefelaer 1982). Among the Tuareg nobles, the service that legitimises marriage (often called '*dot*' in French) and which is intended for the father of the bride must consist exclusively of dromedaries. Only people of low extraction will give the equivalent

in the form of cattle or, worse still, in small ruminants. In some parts of sub-Saharan Africa, the parent-in-law helps the young couple to settle by giving them a dromedary and a well-harnessed horse, a loan of 30 cows with a bull and a donation of about ten cows. Similarly, the newborn receives from his parents, grandparents, 7 days after the birth, a gift of some heads of dromedaries, cows, etc., which already constitute his small patrimony. These show how dromedaries play a leading role not only in marriage but also in the start of the independent life of the new households.

9.4.4 Modern Uses of Dromedary

Because it is rich in vitamins C and contains iron and vitamins A, B1, B2 and B12, dromedary milk is an excellent raw material for cosmetic products. For example, organic dromedary milk soap reduces stains on the face, regenerates cells, deeply moisturises and nourishes the skin and makes it softer. Dromedary fat is also believed by some to be a remedy against rheumatism, osteoarthritis, asthma, hair loss and the treatment of respiratory problems (Agrimaroc 2021).

In Mongolia, a Swiss corporation once helped to develop and promote a line of cosmetic products based on dromedary milk. They introduced a programme to train farmers to produce and supply clean, good-quality milk as raw material to the processing industry. The 'Dromedary act' brand products were made available in stores in the capital, Ulan-Bator and for export (Lhoste et al. 2010).

According to the Swiss corporation, the added value obtained from the dairy products of the Bactrian dromedary increases the income of the producers by 80% on average.

The industrial exploitation of dromedary products (wool and milk) is clearly a way to improve the place of this species in Mongolian agriculture (Agrimaroc 2021). This activity and launch phase in Algeria via the collaboration that was born through the CA.RA.VA.N. The objective was the implementation of a modern dromedary selection system project involving the dromedary owners and the students of the University of Tlemcen through start-up projects for the cosmetic valorisation of dromedary milk and its fat (Lakermi and Sabrou 2021).

A technical innovation developed in India transforms dromedary faeces into paper. The dromedary faecal excretions are characterised by a low nitrogen composition, which makes its manure unsuitable as fertiliser. However, faecal material is rich in indigestible fibres that can be exploited after an adequate treatment in the form of pulp. This process was previously tested on elephant droppings, which are also rich in fibre; however, its development from dromedary droppings is a first. This is happening in India and more precisely in Rajasthan, a region of the country where the dromedary husbandry remains important and where the raw material is not lacking. Products such as diaries, notebooks or postcards made from the fibres of dromedary droppings were presented at the annual Pushkar Fair by the NGO '*Lokhit Pashy-Palak Sansthan'* (LPPS), which extolled this ecological product by pointing out the multi-use valuation permitted by dromedary keeping in the country (CIRAD 2009).

Nanobodies, or single-domain antibodies, have found their way into research, diagnostics, and therapy over the last two decades, according to Beghein and Gettemans (2017) in their review paper (Beghein and Gettemans 2017). These antigen-binding fragments, derived from camelids' heavy chain-only antibodies, have unique properties that make them preferable to conventional antibodies or fragments of antibodies in certain research areas. The authors evaluated nanobodies' current status as research tools in a variety of fundamental research areas. They focused on recent advances in super-resolution microscopy and discussed the use of nanobodies as detection reagents in fluorescence microscopy. Secondly, the use of nanobody technology in studying protein–protein interactions is discussed, with a focus on potential applications in mass spectrometry. It has also been recently reported that nanobodies have applications in targeted protein degradation in a review which discusses their potential value in studying protein

function (Beghein and Gettemans 2017). They highlighted state-of-the-art engineering strategies that could expand nanobody versatility and suggest future applications of the technology in selected fundamental research areas throughout the review.

9.4.5 Dromedary Racing

Dromedary racing was registered in 2020 on the Representative List of the Intangible Cultural Heritage of Humanity. Dromedary racing, a popular social practice and festive heritage associated with dromedaries in the communities concerned. The preparation of a dromedary race includes several stages. Selected dromedaries, according to their type, origin and age, receive a special diet. They are trained on the racetrack in groups to participate in races. Dromedary breeds are organised on designated routes under the supervision of specialised committees in the communities. The demand for special breeds of racing dromedaries, with higher endurance and resilience, is quite high. For each race, there are usually between fifteen and twenty dromedaries competing, and the distance to be travelled is determined according to the age of the animals. Traditions, customs and principles recognised by the communities govern the breeds and practices of the associated communities. In addition, a preparatory committee is responsible for verifying the origin of each dromedary. The transmission of knowledge and know-how is achieved through the joint efforts of community representatives, government agencies, specialised centres, and the federation of breeds and clubs. Children and youth gradually acquire the knowledge and skills associated with practice through observation, simulation and oral expression. The dromedary race is a fundamental aspect of their nomadic way of life as well as a source of inspiration and creativity in poetry and song. Its importance and continuity in Bedouin society are linked to the predominant role of dromedaries in desert areas (UNESCO 2020).

The development of new techniques to measure oxidative stress and endurance in racing dromedaries has very high potential (Wilson 1999). To do this, studies on the mitochondrial DNA (mtDNA) of dromedaries are being undertaken. Indeed, this DNA is 16,643 bp in size and encodes 23 subunits of the electron transfer chain associated with the production of cellular adenosine triphosphate (ATP) by oxidative phosphorylation (Cui et al. 2007). Cells that require a lot of energy in terms of ATP, such as neurons and muscles, maintain high mtDNA copy numbers (Dickinson, 2013). Polyacrylamide gel electrophoresis was used to analyse malate dehydrogenase (Mdh) and malic (ME) isoenzymes in Arabian camels for energy production and running. The results indicated the need for mitochondrial Mdh-2 for energy production in the racing breeds and cytosolic Mdh-1 for lipogenesis and energy production in both racing and non-racing breeds (Pickford et al. 1995). Likewise, the ratio of mitochondrial DNA (mtDNA) to nuclear DNA (nDNA) is also considered to be a good predictor of the metabolic state of the tissue. This ratio was found to be high in racing dromedaries compared to dairy dromedaries (Soman and Tinson 2016). Several regions have declared the dromedary as their flag animal and hold events nationwide to promote and showcase dromedary keeping among local residents.

In the countries of the Gulf, in particular the United Arab Emirates, the dromedary race is a real institution in a similar way to the thoroughbred horses destined for the same activity in the West. The racing stables are maintained with great care, the feeding of the animals, their training, biosecurity and welfare or their protection or their selection fall in all cases under the principles of intensification, the production of these farms being the sporting performance (Faye 1997; Seboussi et al. 2004). The intensification of breeding of racing dromedaries increasingly requires the use of biotechnologies applied to breeding. The perfect knowledge of the physiological peculiarities is indispensable to optimise the interventions in the dromedary species, which is not the least if compared to those of the horse, considered the noble species of the northern countries of the Mediterranean basin (Zarrouk et al. 2003).

In Europe, especially in France, Jockeys compete in the French Dromedary Racing Championship on the racecourse of La Chartre-sur-le-Loir (Sarthe).

In Africa, for example, in Niger, in the region of Ingall, where one of the main racing dromedary breeds of the Sahara is found, breeds are organised for competition in the 'Cure Salée festival', a great celebration of Saharan pastoralism. Although dromedary breeds are not as popular as they are in the Gulf countries, they are nevertheless organised on the occasion of festivities such as the marathon of Douz (Tunisia), the festival of Marrakech (Morocco) or the fantasia of Ouargla (Algeria). The ascent of the dromedary as a saddle animal is also regularly practised in most countries of the Maghreb, especially among the Tuareg (Algeria, Libya) or Saharawi populations (Morocco) (Faye 2014).

9.4.6 Dromedary Trekking and Tourism

Ecotourism has a low impact and is often an alternative to traditional commercial (mass) tourism that involves visiting or encroaching on fragile, pristine and relatively undisturbed natural areas. Environmental conservation includes ecotourism, which requires taking into account the needs of the native communities so as to help them improve their livelihoods. Dromedary keepers know and benefit from the interest maintained in the field of leisure and tourism, in particular touristic activity in the desert, although this activity has decreased in some countries, such as Algeria or Libya, for security reasons. In other contexts, dromedaries are part of the decor for touristic places or sites (dromedary rides at the foot of the pyramids of Giza in Egypt or on the island of Djerba in Tunisia, or in Essaouira in Morocco, to give only a few emblematic examples) (Faye 2014).

The dromedaries hold a place of choice in all aspects of the social life of dromedary drivers (festivals and games). The occasions of local festivals are where the fantasia is omnipresent, attracting a large audience at the same time. In Morocco, for example, owners supply dromedaries or their services to tourists to rent. They may also rent their whole herd to hotel owners or intermediaries who are in contact with tourist agencies, which allows keepers and their families to earn income and meet their daily needs. Moreover, they do not define themselves as keepers but rather as 'organisers of dromedary treks'. During the high tourist season, they keep their dromedaries in enclosures in the villages. In the low tourist season, they are released, and keepers will take care of their watering. The development of touristic activity has consequently led to the emergence of a new husbandry system (Faye 2014).

9.4.7 Other Uses of the Dromedary

The dromedaries are, unfortunately, also used in public fights. These are organised based on the fury of the male in the period of rut; the fighting animals are muzzled to avoid possible injuries. The dromedary is an element of the return to the source, an unfailing companion. It is therefore an important element in the touristic walks in the Sahara in a desolate universe and in complete break with modernity. Coated animals are bred for the needs of the film industry in the studios of the Atlas in Ouarzazate, Morocco (Camps et al. 1996).

A Case Study of Tsabong Ecotourism Park

A study with the aim of assessing herd size, composition, dromedary types, revenue sources, the role of dromedaries in ecotourism and benefits to communities using the Purposive Sampling Technique was conducted at Tsabong Ecotourism Dromedary Park (Botswana) by Seifu et al. (2018). A semi-structured questionnaire was developed and used to interview key informants. Field observations were also carried out to assess the conditions of the dromedary herd and facilities. The results showed that dromedaries in the Park were used for riding by tourists. Respondents mentioned that the dromedary riding safari was the main touristic activity provided by the Park. According to key informants, the

Park's income was derived from both dromedary- and non-dromedary-related activities. Dromedary riding, trekking, wedding ceremonies, photographs and entrance fees were dromedary-related income sources. Informants' experiences showed an increase in the trend of tourists visiting the Park between 2015 and 2017. The results showed that the Park hosted more local visitors than foreigners, with locals accounting for 91% of visits. Improved promotion is required to attract international tourists to the Park. Dromedary racing seems to be one of the potential business areas to attract tourists to Botswana. Such efforts would improve incomes and livelihoods in the local communities and strengthen a sustainable tourism attraction.

9.5 Dromedary and Environment

The dromedary thrives in the harsh and very restrictive desert conditions of the Saharan ecosystem, where it not only survives but also manages to reproduce and even produce meat and milk. It is the only domestic species capable of valuing this vast, inhospitable environment, thanks to different parameters of adaptation (Chehma and Faye 2009). Faye and Tisserand (1989) cited in Faye and Tisserand (1989), showed that the dromedary requires less water per unit of dry matter ingested and digests more plant walls and less dietary nitrogen than sheep (Faye and Tisserand 1989). It does not require lush forages, but only highly salted forages that are well adapted to the arid areas (Chehma 2005).

The dromedaries are capable of consuming several types of food, some of which are rejected by ruminants. The plant species consumed by the dromedary vary from legumes, grasses, forage trees, and herbaceous to woody plants. Its feed ration comprises 90% of woody forage in the dry season and about 50% in the rainy season (Faye and Tisserand 1989). It eats very thorny plants also for the bitter taste. This makes the dromedary an animal suitable for mixed grazing with other domestic species, where it does not compete with them for feeding resources (Gauthier-Pilters 1977). The technique of feed harvesting, by "brushing" the branches by pressing them laterally in his mouth, allows him to unstuck, without difficulty, the branches of the most thorny woody (Richard 1995).

Although this animal is selective, it does not cause degradation in rangelands. On the contrary, it contributes to the conservation of its extremely fragile ecosystem. It also plays an important role in the regeneration of certain species of plants that germinate only through the digestive tract of this animal (Longo et al. 2007). Unlike small ruminants and cattle that cause intense overgrazing around water points, it behaves solitarily on the rangeland, avoiding overload that causes the degradation of vegetation and the environment. It is able to stabilise its annual nutrient intake, despite temporal fluctuations caused by climate irregularity in its environment (Chehma and Faye 2009).

In general, the dromedary has a set of adaptation mechanisms that make it the animal of choice for the Saharan areas. This choice is more necessary in view of the need to satisfy the nutritional needs of the populations living in these regions, to restore the balance of these ecosystems and the maintenance of certain plants that contribute to the stabilisation of dunes (Faye and Tisserand 1989; Trabelsi et al. 2012).

9.6 Reproduction

During the rutting season, the dromedary becomes aggressive towards other dromedaries and towards its owner and can be extremely dangerous. A horny male grinds his teeth, whips his tail, wags his head and neck, foams at the mouth and urinates frequently, splashing urine all around. Rutting is a period of high sexual activity for a limited time, presumably controlled by the level of testosterone (Gherissi et al. 2017). The heat can be induced by treatment with gonadotropins and better nutrition (El-Bahrawy et al. 2015). Dromedaries are seasonal breeders, but the activity of males is more affected than that of females. With regard to males, the seasonal breeding behaviour of the male dromedary

is called 'rut'. It is usually expressed for the first time around when the animal is aged 3 years (Gherissi et al. 2020b). Males in heat become more aggressive, and the size of the testes increases. In the presence of a female or other male in sight, they stand with their legs apart, pour urine on the back with the tail, foam at the mouth while making gurgling noises and overtaking their Dulla. The pollen glands become active and exude a dark, acid secretion, which seems to attract females (El-Bahrawy et al. 2015).

Females, separated from the males, will emit a gurgling sound, almost similar to that of the male in heat, when ready to mate. She will get as close as possible to the male as far as the situation allows. For controlled mating, the traditional procedure is to take the female to a sandy location and lay her down with her head slightly down the hill, if possible. About 50% of females ready for mating spontaneously lie down when approaching the male. Others, especially young animals, may be forcibly restrained in a supine position with the front legs tied together around the animal's neck. In a free mating situation, the male will dominate while battling the female on the ground. Coitus takes place with the female lying down. The male covers the female by placing one foreleg on either side of the female's hump, her pedestal on her dorsal midline behind her hump, and squats back and down in the coital position. Depending on the relative sizes of male and female, the male's foreleg may or may not reach the ground (Khan et al. 2003).

According to Cherifi et al. (2013) the reproduction and weaning for dromedaries take place during the period of low temperatures and heavy rains and when the grass is of high quality (Cherifi et al. 2013). The breeding season extends from November to April in the south-western Algeria, but it is really intense from December to February (Gherissi et al. 2018). The farmers have developed reproductive strategies enabling them to optimise the genetic quality of their animals according to the constraints imposed upon them by the environment. The management of reproduction is characterised by close cross in the same herd that reduces genetic variation and increases inbreeding. As the breeding season approaches, breeders who do not have a breeding male borrow one from other keepers and introduce it to their flock for mating. This practice is free of charge and rather is part of the good social relationship among neighbouring breeders.

The herd of females in hot weather is constantly guarded by the breeding males, sometimes in groups, in order to more accurately determine when they come into heat. According to the farmers, one breeding male is enough for a herd of 20–50 females. For those with large herds, the presence of 2 or 3 breeding males is common.

Weaning of dromedaries is practised between 8 and 18 months, and an average age of about 12 months. This, however, depends on the mother and her diet. The smaller calves tend to stay with their mother for over a year, especially if the mother is not pregnant during the second year. Voluntary withdrawal of dromedaries is rare in these regions, as in most cases, calves are weaned by their mothers very often at the age of 1 year.

Gherissi et al. (2020a) conducted a survey which was aimed at evaluating dromedary herds' fertility and fecundity under Algerian extreme arid conditions (Gherissi et al. 2020a). Progeny history testing data obtained from 14 dromedary herds (78 females and 20 males) was analysed and compared with standard objectives and thresholds. The age at first rut, the first oestrus, and the first male and female mating (months ± SD) were 37.2 ± 16.29 months, 31.07 ± 8.97 months, 42.6 ± 14.28 months and 35.52 ± 8.55 months, respectively. The birth-to-conception interval, open days, age at first calving and calving interval were 40.35 ± 9.41 months, 340 ± 203 days, 51.05 ± 9.59 months and 22.32 ± 5.63 months (Gherissi et al. 2020a). The mean male-to-female ratio was 1:40 (Gherissi et al. 2020a). Pregnancy diagnosis was performed 21.81 ± 16.4 (days) post-mating, and the duration of pregnancy was on average 12.80 ± 0.30 months (Gherissi et al. 2020a). The mean herd's annual fertility was 56.2 ± 6.6%; the mean culling age of males per herd was 15.30 ± 2.47 years, whereas females were culled at 23.31 ± 5.64 years with a mean number of 5.23 ± 2.91 lactations (Gherissi et al. 2020a). However, all the considered herds

showed annual fertility out of threshold. The lack of a significant strategy to improve age at first calving, calving interval and selective use of dromedary bulls is likely to affect fertility and productivity of Algerian dromedary herds. Such a negative trend could hamper the genetic improvement of autochthonous dromedary ecotypes and compromise the dromedary sector and the ecosystem services provided by local cameleers (Gherissi et al. 2020a).

It is becoming obvious that the classical system of reproduction cannot respond to the increased importance of dromedary breeding in Africa (and around the world) and especially in the deserts and in newly reclaimed areas. To overcome this, the Artificial Insemination and Embryo Transfer Laboratory, Mariout Research Station, Alexandria, Egypt, has conducted several studies for over a decade to improve the reproductive performance of dromedaries by developing assisted reproduction techniques (Rateb et al. 2020). Gherissi and Lamraoui (2021) have highlighted different pharmacological and biological strategies for the management of dromedary reproduction (Gherissi and Lamraoui 2021). These authors indicated different methods used to improve the cryopreservation capacity of sperm by enriching diluents with additives as well as developing procedures to remove viscosity from dromedary sperm intended for fresh, short-term and long-term conservation (Gherissi and Lamraoui 2021). Finally, a comparison of the conception rate of female dromedaries according to different sperm conservation methods showed wide variability due to conservation time, method, semen quantity, dilution method, extenders and post-throw insemination (Gherissi and Lamraoui 2021).

With regard to females, new techniques and modalities for the induction of multiple synchronised ovulations have been extended, while the practical detection of oestrus in the field has, for the first time, been appropriately determined. In addition, the use of sophisticated molecular genetic techniques to identify the potential fertility of males has been attempted. The development of an in vitro fertilisation procedure and the production of unconventional embryos by intracytoplasmic sperm injection (ICSI) have also been described.

9.7 Some Dromedary Diseases in Africa

For generations, nomadic pastoralists have learnt to manage their herds' health, and particularly their dromedaries, because of the great financial value of these and the capital they represent. They thus acquired a very detailed knowledge of the signs of disease in this species, which they classify and name according to specific systems. The pathologies reported by keepers as being the most worrying in their opinion are gastrointestinal verminosis, dromedary's diarrhoea, tick infestations, smallpox, sarcoptic mange and bronchopneumonia. The presence of misidentified entities is also reported (Antoine-Moussiaux et al. 2006). As a result, we report here two diseases (Prion disease and trypanosomiasis) not reported by many owners, but with a high risk of spreading rapidly in Africa. Indeed, the rush of humans for energy has made the Sahara a dumping ground for household waste, especially some of which are toxic for the dromedary (Babelhadj et al. 2018). These are believed to be the first cause of the onset of prion disease. Also, the development of Saharian agriculture has led governments to create water points, which for the most part, attracted the tsetse fly, the main vector of trypanosomiasis.

9.7.1 Prion Diseases

Human Creutzfeldt–Jakob disease (CJD), scrapies in small ruminants and bovine spongiform encephalopathy (BSE) are all fatal and transmissible neurodegenerative diseases caused by prions. Following the outbreak of BSE and related human infections in the United Kingdom in 1996, animal prions sparked widespread concerns. As a result of these concerns, a large number of countries have begun to implement surveillance strategies in order to prevent the disease. Thanks to collaboration between Algerian and Italian

researchers, a prion disease in dromedaries (*Camelus dromedarius*) was discovered in Algeria. In the years 2015–2016, 3.1% of dromedaries brought to the Ouargla slaughterhouse showed signs of prion disease. Pathognomonic neurodegeneration and disease-specific prion protein (PrPSc) were found in brain tissue from three symptomatic animals, confirming the diagnosis. Prions have been discovered in a variety of animals. The presence of prions in lymphoid tissue suggests that the disease is infectious. The biochemical profile of PrPSc differed from that of BSE and scrapies. The discovery of this prion disease in a widely farmed species necessitates the immediate implementation of surveillance and risk assessments for human and animal health (Babelhadj et al. 2018). The lack of effective preventive and therapeutic approaches against prion diseases represents a serious problem for their management. This is especially true for animal prion diseases, which behave like infectious and contagious diseases. In the case of scrapies, the well-known role of variations in the prion protein gene (PRNP) in resistance/susceptibility represents an opportunity that has been exploited to select populations genetically resistant to the disease and therefore the possibility of eradicating this disease. Kaouadji et al. (2020) studied a dromedary prion disease (CPrD) in Algeria while investigating the possible existence of genetic determinants useful for a selection of the most resistant animals (Kaouadji et al. 2020). In this work, researchers studied the variability of PRNP in 232 animals from six populations of dromedaries (Azawad, Hybrid, Naili, Rguibi, Sahraoui and Targui) in Algeria. A Gly69Ser mutation was observed in a single animal from the Targui population and a Gly134Glu polymorphism in the Azawad, Hybrid and Rguibi populations, with a frequency of the 134 Glu allele of 2.6%, 7.7% and 7.1%, respectively. Although this work highlights a low variability of PRNP in Algerian dromedaries, as a possible indication of a recent evolutionary history of CPrD, it also provides evidence for PRNP variants whose role in resistance/susceptibility to prion diseases deserves to be deepened via a case-control. Dromedary keepers currently have no other solution than culling animals suffering from this disease. The investigation by neurologists in the region of Ourgala, where the disease was detected in Algeria, did not reveal the presence of any patient with CJD, showing a non-zoonotic pattern in this case.

9.7.2 Dromedary Trypanosomiasis

In Somalia, which has the world's largest population of dromedaries (*Camelus dromedarius*), dromedary trypanosomiasis, or surra, is a major concern. As a result of the civil war in Somalia, the country's educational, research, economic and social structures were destroyed, and the country scored very low on most humanitarian indicators. Previous studies on the detection of Trypanosoma species in Somali dromedaries, which used standard trypanosome detection methods, were only conducted in the 1990s (STDM). Due to a lack of current knowledge on dromedary trypanosomiasis in Somalia, the goal of this study was to determine the prevalence of *Trypanosoma* spp. in three Somali districts. A total of 182 *C. dromedarius* blood samples from nomadic and dairy farms were tested using STDM, serological (CATT/*T. evansi*) and PCR methods.

A total of 125/182 (68.7%, 95% CI: 61.4–75.3%) dromedaries were seropositive for *T. evansi* by CATT/*T. evansi*. Dromedaries reared in a nomadic system were more likely to be seropositive for *T. evansi* than those reared in a dairy system (OR: 5.6, 95% CI: 2.1–15.2, P = 0.0001). Five out of 182 dromedaries (2.7%, 95% CI: 0.9–6.3%) tested positive for *Trypanosoma* sp. by ITS1-PCR. Sequencing of the ITS1 region of the *Trypanosoma* species detected here revealed that the dromedaries were infected with *T. evansi* and *T. simiae*. These researchers conclude that *Trypanosoma evansi* is widespread in dromedaries in the Banadir region of Somalia, especially in nomadic herds. This study is the first to confirm *T. evansi* and *T. simiae* infections in Somali herds by DNA sequencing. These data highlight the need to implement adequate control measures aimed at reducing the impact on dromedary production in the country (Hassan-Kadle et al. 2019).

By another approach, Nowier et al. (2020) aimed in their studies at estimating firstly the polymorphism of the tyrosinase (TYR) gene in four breeds of Egyptian dromedaries (Nowier et al. 2020), on the other hand, to estimate the body and udder measurements of the most important dromedary breeds in Egypt (Maghrebi) and thirdly, to study the possible association between the polymorphism of the TYR gene and measurements of the body and udder of the Maghrebi breed (Nowier et al. 2020). Hair samples were taken from 124 female dromedaries belonging to four Egyptian breeds: Maghrebi (n = 70), Sudani (n = 17), Somali (n = 25) and Falahy (n = 12) for the extraction of DNA. Fourteen body measurement traits and twelve udder traits were evaluated for 35 female Maghrebian dromedaries. The non-synonymous C/T SNPs of the TYR gene were genotyped using the restriction enzyme DdeI. Among the four dromedary breeds studied, the heterozygous CT genotype recorded the highest frequency (45%). Our results showed that the C/T SNP of the TYR gene had a significant association with neck length (NL), height at withers (HW) and chest circumference (TG), with the highest values observed for individuals carrying the CT genotype. In addition, this study showed that the SNP C/T of the TYR gene had a significant association with teat separation (TS) and teat distance (TFD) traits, with the highest values observed for dromedaries carrying CC and CT genotypes, respectively. The information from this study may be useful in designing an appropriate breeding and breeding strategy for optimal use and improvement of the genetic resources of the Egyptian dromedary.

Currently, an important collaborative work between Algeria (University of Tlemcen) and Egypt (University of Ain Shems) is launched on the genetic investigation concerning the detection of *Trypanosoma* species using molecular tools and bioinformatics. Preliminary results indicate that a significant prevalence of this agent exists in these areas with a great diversity of species. Currently, keepers lacking medication rub used engine oil on wounded skin caused by the disease.

9.8 State of Diversity of Dromedary in Africa

The invention of agriculture (horticulture) and animal husbandry provides mankind with greater food security, and the population has made a leap forward. The second leap that humanity made was due to another revolution; the Industrial Revolution. In a few hundred years, major cities will have occupied considerable areas on the planet. These concrete jungles replaced other real ones and devoured vast territories and rural habitats. The speed at which they have spread has left little time for evolutionary adaptations. These sudden changes have put an end to many species, and some are undoubtedly disappearing even before their existence has been realised. Each species is a library of information acquired by evolution over hundreds of thousands, if not millions, of years. We are losing entire libraries. Unfortunately, despite the effects of biodiversity loss (less food security, climate change, etc.), humanity is not aware of what is lost in terms of wealth (Gaouar 2009).

Preserving this heritage, therefore, becomes a necessity in order to keep a genetic reservoir capable of responding to future global constraints. This strategic goal can only be achieved through the mandatory passage of existing biodiversity knowledge. In Africa, more than anywhere else, the need for this stage is felt even more. To do this, several levels and techniques of biodiversity analysis were undertaken by the researchers on dromedary genetic resources.

9.8.1 Morpho-Biometric Studies

According to Gaouar (2009), this method, commonly used to characterise and compare breeds of livestock (goats, sheep, cattle, camels and equines), is a good start for a better knowledge of domestic breeds in Africa (Gaouar 2009). Indeed, there is a lack of classical means and studies to identify and exploit the dromedary's biological potential. There is a great need for standardised approaches. These include the identification of genotypes adapted to different conditions (feed

availability, heat resistance, etc.) as well as the analysis of phenotypic characteristics (morpho-biometrics) to establish an available preliminary database that will contribute positively to the better use and promotion of the dromedary resource.

The phenotypic characters were the first traits used for the selection and definition of breeds, it is the result of the animals features observation (coat colour, leg conformation, morphology of the head and body, etc.), or morphological measurements (height, weight, body width, etc.), or performance measurements (growth rate, dairy production, hair production, etc.).

In addition, the similarity between morphological traits can be considered a reflection of a genetic identity, but this may be due to different alleles or genes at different loci. A difference in phenotypic expression can be explained by a real difference at the genetic level, but it can also be due to a variability of expressivity or penetrance of the genetic and/or climatic environment (Gaouar 2002).

These considerations limit the use of morphological characters as elements for the reconstruction of the phylogeny of breeds and their characterisation (Gaouar 2002).

Alhajeri et al. (2021) and Gherissi et al. (2022) propose a new approach to data collection for more interesting morphometric and precise morphometric data (Alhajeri et al. 2021; Gherissi et al. 2022). In broad distribution, animals exhibit large phenotypic variation, which so far has mostly been examined using traditional distance-based morphometric approaches. The narrow sampling of breeds and geographic locations, as well as the relatively few and ambiguously defined morphometric measurements, which often do not cover all functionally important traits, are the main pitfalls of previous studies. So, these researchers offer some suggestions for standardising morphometric data collection, as well as an overview of more advanced methods for capturing morphometric data in dromedaries. This would make data collection much easier in these animals, which can be difficult to work with at times. Moreover, its applicability to breed identification and delimitation was studied for a variety of purposes. Finally, they suggest possible applications for these morphometric studies, particularly in the context of developing breeds specialised for specific purposes such as meat, milk and leather production.

Several papers on African dromedary breeds using the morphometric approach have been published. Chniter et al. (2013) identified five groups of Maghrebi camels in southern Tunisia based on tribal affiliation (Chniter et al. 2013): the *Ourdhaoui Médenine* in the Tawazins tribe, the *Ourdhaoui Tataouine* in the Oudarna tribe, the *Guiloufi* in the Beni Guilouf tribe from Kébili, the *Gueoudi* in the Ouled Gharib tribe from Kébili. The nine body measurements taken include the body length, length of the neck, thoracic girth, abdominal circumference, height at the hump, height at the withers, width between shoulders and height at the withers, the length of the anterior limb and the length of the tail. The height at the hump and the height at the withers, the thoracic girth and the abdominal circumference, and the length of the body and the length of the neck all showed a positive correlation. The length of the tail, on the other hand, had a negative relationship with the abdominal circumference and withers height. When compared to the Ourdhaoui Médenine dromedary group, the Gueoudi, Guiloufi and Merzougui dromedary groups had longer bodies and larger abdominal circumferences. In comparison to Ourdhaoui Médenine, the Guiloufi, Merzougui and Ourdhaoui Tataouine dromedary groups had the highest thoracic girth and height at the withers. In comparison to the Gueoudi, Guiloufi and Merzougui dromedary groups, the Ourdhaoui Médenine and Ourdhaoui Tataouine dromedary groups had the longest tails. The five groups were clustered together, allowing three main classes of Maghrebi dromedaries to be described: large, medium and small size Maghrebi camels. Six vernacular names were identified based on coat colour: Chagra, Chaâla, Safra, Hajla, Hamra and Zarga. Because the hair was mostly rough and thick, the female dromedary was given the name Nagga Chalfi. Females with sleek and heavy hair, known as Nagga Khawar, were given a small portion of the population.

Boujenane et al. (2019) looked at 14 body measurements from 132 adult female dromedaries from three different populations (Boujenane et al. 2019). Guerzni (60), Khouari (28) and Marmouri (44) were reared in 38 herds across eight Southern Moroccan provinces in order to identify homogeneous groups based on conformation. Chest girth (CG), hump girth (HG), height at withers (HW), body length (BL), fore limb length (FLL), chest width (CW), chest depth (CD), fore hoof circumference (FHC), head length (HL), distance between eyes (DE), ear length (EL), neck length (NL), neck circumference (NC), and tail length (TL) were the measurements. Multivariate analyses were used to compare the three populations based on their mean body measurements. Only HG, HW, BL and FLL were found to be significantly influenced by the population. Furthermore, the MANOVA revealed that the Guerzni and Marmouri populations differed significantly, whereas the Khouari population did not differ significantly from the Guerzni or Marmouri populations. Out of 14 variables, discriminant analysis revealed that BL and FLL were the most discriminant, resulting in two significant canonical variables (CAN1 and CNA2). CAN1 could best distinguish the Khouari population from Guerzni and Marmouri, and CAN2 could best distinguish Guerzni from Marmouri. According to the discriminant analysis, 46.7% of Guerzni, 60.7% of Khouari and 40.9% of Marmouri animals were correctly classified in their original population. Two Moroccan dromedary groups emerged from the clustering of the three populations: Guerzni and Marmouri in the first and Khouari in the second.

Meghelli et al. (2020) recently conducted a study using body measurements to identify two different dromedary breeds reared in Algeria (Meghelli et al. 2020). A total of 115 animals from the Steppe (n = 55) and Sahraoui (n = 60) dromedary breeds made up the study's animal material. Body measurements like head length, neck length, neck girth, tail length, distance between eyes, distance between ears, body length, withers height, chest girth and live weight were determined, as well as eye and coat colours. The least squares means for head length, neck length, neck girth, tail length, distance between eyes, distance between ears, body length, withers height, chest girth and live weight for Steppe and Sahraoui dromedary breeds, respectively, were 48.2, 116.9, 65.7, 55.6, 24.1, 22.5, 152.2, 184.5, 141.2 cm and 217.2 kg for Steppe and 48.1, 101.2, 56.2, 51.2. The Steppe dromedary breed had a distribution of brown and black eye colours of 58.2% and 41.8%, respectively, while all of the Sahraoui dromedaries studied had brown eyes. Coffee, dark coffee and red colours account for 1.8%, 83.6% and 14.6% of the Steppe dromedary's body colour, respectively, and 98.3%, 1.7% and 0.0% for the Sahraoui dromedary, respectively. As a result, this study concluded that the height at withers and chest girth could better estimate the body weight in the two breeds of dromedaries at different ages (Meghelli et al. 2020). In another study, Legesse et al. (2018) examined seventeen morphometric variables to determine intraspecific variation among eight pastoralist-designated breeds of dromedaries (Legesse et al. 2018).

9.8.2 Immunogenetic or Biochemical Studies

Knowledge of the variability of biochemical markers makes it possible to develop hypotheses about the origin of animal populations and to determine the relations between breeds of the same population or species. Immunogenetic markers include blood groups' polymorphism and blood proteins (Martins et al. 2002). This type of marker has the advantage of giving more precise information on the physiological differences of the studied populations and therefore on their zootechnical potential. Protein polymorphisms were the first markers to be used in livestock.

The biochemical and haematological blood profile in Libyan dromedaries was described by Abdalmulaa et al. (2019), and the effects of breed, gender and age on these values were evaluated (Abdalmulaa et al. 2019). The levels of enzymes, metabolites, electrolytes and hae-

matological indices were measured in blood samples taken from 24 male and 42 female apparently healthy dromedaries (Abdalmulaa et al. 2019). Male dromedaries had higher levels of aspartate aminotransferase (AST), Lactate dehydrogenase (LDH), Amylase (AMS), total proteins, globulin and phosphorus (Ph) in their blood than female dromedaries, which had higher levels of glucose, albumin/globulin (A/G) ratio, urea, Iron (Fe), Calcium (Ca) and Packed Cell volume (PCV) in their blood, Haemoglobin (Hb), erythrocyte osmotic fragility, Mean Corpuscular Volume (MCV), the number of neutrophils and monocytes, as well as the mean corpuscular volume (MCV) and mean corpuscular haemoglobin (MCH). Many haematological and biochemical analyses reveal significant sex differences between male and female Libyan dromedaries in this study (Abdalmulaa et al. 2019).

9.8.3 Molecular Studies in the Dromedary

Recent major developments in molecular genetics have provided new and powerful tools, called molecular markers, to assess the origins of farmed animal species and their geographic distribution as well as their diversity (Duran et al. 2009).

Nuclear markers, which increasingly number in ranges from Restriction Fragment Length Polymorphism (RFLP), Amplified Fragment Length Polymorphism (AFLP), to microsatellites or 'Single Tandem repeat': tandem repeated sequences (STR), Mitochondrial DNA polymorphisms (mtDNA) and recently single nucleotide polymorphisms (SNPs), have become the markers of choice for studying the genetic structures and evolutionary history of organisms (Fitak et al. 2016).

Molecular marker technologies offer the most advanced and likely most effective way to understand the fundamentals of genetic diversity. They are effective and precise tools for identifying and measuring genetic variation quickly and thoroughly.

Genetic diversity and relationships among dromedary (*Camelus dromedarius*) populations have been poorly studied. Yet, understanding the genetic diversity and structure of dromedary populations is critical for long-term herd management and the implementation of breeding programmes in this species. Mburu et al. (2003) used 14 microsatellite loci to study four recognised Kenyan dromedary breeds (Somali, Turkana, Rendille, Gabbra) as well as dromedaries from Pakistan and the Arabian Peninsula (Saudi Arabia, United Arab Emirates) (Mburu et al. 2003). Phylogenetic analysis indicated that Kenyan dromedaries are distinct from Arabian and Pakistani populations. The Kenyan dromedaries were less diverse relative to non-Kenyan populations based on the expected heterozygosity and allelic diversity values. The Kenyan dromedaries were poorly differentiated (average FST = 0.009), with only one to two loci separating the Gabbra, Rendille and Turkana populations studied ($P < 0.05$), with the exception of the Somali population. Individual assignments were performed using the maximum likelihood method. When using an allocation stringency of a log of the odds ratio > 2, a correct breed assignment of only 39–48% was observed for Kenyan dromedaries. The findings refute the current classification of the native Kenyan dromedary into four distinct breeds based on socio-geographical factors. Instead, these findings point to only two genetic entities: Somali type and a group that includes Gabbra, Rendille and Turkana populations.

In the same context, Cherifi et al. (2017) characterised a total of 331 dromedaries from Northern Africa, representative of six populations and thirteen Algerian and Egyptian geographic regions, using 20 STR markers (Cherifi et al. 2017). The nineteen polymorphic loci displayed an average of 9.79 ± 5.31 alleles, ranging from 2 (CVRL8) to 24 (CVRL1D). Average: He was 0.647 ± 0.173. Eleven loci deviated significantly from Hardy-Weinberg proportions ($P < 0.05$), due to an excess of homozygous genotypes in all cases except one (CMS18). Distribution of genetic diversity along a weak geographic gradient, as suggested by network

analysis, was not supported by either unsupervised or supervised Bayesian clustering. Traditional extensive/nomadic herding practices, together with the historical use as a long-range beast of burden and its peculiar evolutionary history, with domestication likely occurring from a bottlenecked and geographically confined wild progenitor, may explain the observed genetic patterns.

Additionally, DNA sequences from the mitochondrial cytochrome-b gene and genotyping of six nuclear microsatellite loci were examined to assess genetic diversity and phylogenetic relationships of Ethiopian dromedaries. Examination of 525 individuals revealed significant morphometric differentiation in Afar as compared with the remaining seven breeds. Analysis of cytochrome-b sequences failed to recover monophyletic groups associated with pastoralist-recognised breeds. Analysis of six microsatellite loci from 104 individuals depicted no resolution of distinct genetic lineages in accordance with geographical or designated breeds. Overall, the separation of two ecotypes based on the morphometric data was supported; however, genetic analysis of cytochrome-b and microsatellite data failed to support any unique genetic lineage or statistically significant population structure.

In the other context of gene identification, Holl et al. (2017) aimed at identifying the genetic origin of the white spotting phenotype in dromedary (Holl et al. 2017). This study includes animals from Africa and Asia. While the typical Arabian dromedary is characterised by a single coloured coat, there are rare populations with white coat spotting patterns. White coat spotting patterns are found in virtually all domesticated species but are rare in wild species. Theories suggest that white spotting is linked to the domestication process and is occasionally associated with health disorders. Though mutations have been found in a diverse array of species, fewer than 30 genes have been associated with coat spotting patterns, thus providing a key set of candidate genes for the Arabian dromedary. We obtained 26 spotted dromedaries and 24 solid controls for candidate gene analysis. One spotted and eight solid dromedaries were whole-genome sequenced as part of a separate project. The spotted dromedary was heterozygous for a frameshift deletion in KIT (c.1842delG, named KITW1 for White spotting 1), whereas all other dromedaries were wildtype (KIT+/-KIT+). No additional mutations unique to the spotted dromedary were detected in the EDNRB, EDN3, SOX10, KITLG, PDGFRA, MITF and PAX3 candidate white coat spotting genes. Sanger sequencing of the study population identified an additional five KITW1/KIT+ spotted dromedaries. The frameshift results in a premature stop codon five amino acids downstream, thus terminating KIT at the tyrosine kinase domain. An additional 13 spotted dromedaries tested KIT+/KIT+, but due to phenotypic differences when compared to the KITW1/KIT+ dromedaries, they likely represent an independent mutation. Our study suggests that there are at least two causes of white spotting in the Arabian dromedary, the newly described KITW1 allele and an uncharacterised mutation.

Whole-genome-wide identification and annotation of genetic variations in dromedaries is in its first steps. In their study, Khalkhali-Evrigh et al. (2018) have identified a total of 4,727,238 single nucleotide polymorphisms (SNPs) and 692,908 indels (insertions and deletions) were found by mapping raw reads to the dromedary reference assembly (Gen Bank Accession: GCA_000767585.1) (Khalkhali-Evrigh et al. 2018). *In-silico* functional annotation of the discovered variants under study samples revealed that most SNPs (2,305,738; 48.78%) and indels (339,756; 49.03%) were located in intergenic regions. A comparison of the identified SNPs in Iranian dromedaries with those of the African dromedary (Bio Project Accession: PRJNA269274) indicated that they had 993,474 SNPs in common. The authors found 15,168 non-synonymous SNPs in the shared variants of the studied dromedaries that could affect gene function and protein structure. Some other genetic studies concerning molecular disease analyses are reported in the previous Chapter (see Chap. 7).

9.8.4 Conservation Programmes of Dromedary Genetic Resources in Africa

The Convention on Biological Diversity (CBD) plays a crucial role in ensuring the sustainable management of animal genetic resources (AnGRs), including the dromedary camel, to meet future needs in various sectors such as food production, fibre, fertiliser and traction. These resources provide essential inputs for agriculture and contribute to the resilience of farming systems, enabling farmers to adapt to changing production conditions effectively. Chapter 25, focusing on the Conservation and Management of AnGR, delves into the fundamental aspects of managing and conserving these resources. It discusses strategies and approaches tailored to different conditions under which animals or 'materials' are managed, emphasising the importance of biodiversity conservation and sustainable use. Additionally, Chap. 30 addresses policy frameworks, strategies and plans essential for safeguarding AnGRs, aligning with the objectives outlined in the CBD. By integrating conservation efforts into policy development and management strategies, stakeholders can ensure the long-term viability of dromedary camels and other AnGRs while promoting agricultural sustainability and resilience in the face of evolving production challenges.

Conservation efforts for African dromedary camels necessitate tailored strategies to address the continent's unique challenges and diverse ecosystems. Genetic resource management initiatives focus on developing breeding programmes specifically designed for African dromedary camel populations, aiming to both preserve and enhance genetic diversity. This involves establishing comprehensive databases and genetic repositories within African countries to catalogue and safeguard valuable genetic information. Concurrently, selective breeding programmes prioritise traits endemic to African dromedaries while mitigating the risk of inbreeding, thus safeguarding the resilience of these populations. Conservation breeding centres, strategically located across African countries, serve as vital hubs for controlled breeding efforts, ensuring the preservation of rare genetic variants and preventing genetic bottlenecks. Community engagement lies at the heart of conservation endeavours, with initiatives targeting local herders to promote sustainable husbandry practices that support genetic diversity. By educating communities about the importance of maintaining diverse breeding stocks and preserving traditional breeding techniques, conservation efforts are deeply integrated into local cultures. Genetic monitoring programmes, specific to African dromedary camel populations, facilitate ongoing assessment of genetic diversity levels and identify emerging threats. This research-driven approach enables the development of contextually relevant conservation strategies, addressing the intricacies of African ecosystems. Through international collaboration, African countries leverage shared expertise and resources to bolster conservation efforts, ensuring that genetic management practices are standardised and effectively implemented across diverse African regions.

9.9 Conclusion and Future Perspectives

Large camelids are undeniably under renewed interest in many fields of research around the world. The scientific community is getting organised to give their research recognition commensurate with the challenges to which these species are called upon to respond (CIRAD 2022). Many projects have been carried out on this animal, especially after the ecologists gave the alert of an unavoidable and global climate change. Dromedaries are found throughout Northern and Eastern Africa, the Middle East and parts of Asia, where they represent an extremely important animal species for millions of people who live in remote ecosystems (arid areas) of the planet. Possibly originated in Arabia or Somalia, the dromedary camel is therefore sometimes referred to as the Arabian or East African camel. After extensive bibliographic research, the present Chapter summarised the mosaic of camel breeds

or genepools in Africa. It is characterised by a panoply of ecotypes, landraces and varieties, which bear various names that often refer to their origin and owning tribe(s), their distribution area, their coat colour, their characteristics and their use… but several of them belong to the same animal type, as attested by molecular genetics analysis, showing the great confusion in the description of African dromedary biodiversity in many African countries and little or no genetic differences between them. In this manuscript, we have processed the classification notion of African indigenous dromedary populations (in 18 African countries) and the introduced dromedary populations in order to provide exhaustive information allowing us to distinguish the ethnozoo-technical particularities of each group. The concepts of dromedary selection and purebred breeding, cross-breeding and interspecific cross-breeding in camel species were taken up to discuss the prospects of these breeding practices on the African continent. In addition, the manuscript reminds us of the morpho-biometric, immunogenetic, biochemical and molecular studies undertaken on the scale of African dromedary populations to expose the state-of-the-art on the biodiversity of dromedaries in Africa. On the other hand, the manuscript also contains a synthesis of the main facilities and organisations of the dromedary sector in Africa and describes dromedary breeding systems in Africa by highlighting the diversity and production potential, pharmacopoeia aspects of dromedary products, the sociocultural roles and the traditional uses of the dromedary in African communities, the environmental roles of this species and the modern uses of dromedary species, and its contribution in trekking, racing and tourism… Finally, through this chapter, we have been able to formulate the essentials of in situ and in vitro conservation practices and technologies for the camel population of African countries.

Unfortunately, our investigations show that most of the African countries where the dromedary can make a difference are affected by many challenges, namely, the lack of advanced technologies in the field of breeding and proper policies to take full advantage of this animal. The policy maker-researcher-breeder relationship should then be strengthened in African countries to advance the development of this almost native rich animal genetic resource.

Abstract

The African continent is a leading producer of donkeys in the world, with major concentrations in the arid and semi-arid environments. Notwithstanding, the donkey remains the least studied among major livestock species despite its enormous support to low- and middle-income communities. The first two sections of this Chapter (Sections 10.1 and 10.2) provide a comprehensive overview of current statistics of donkey production by regions in Africa, as well as the centre of origin of domestication and possible routes of dispersion in Africa. Section 10.3 is dedicated to discussion on 27 different African donkey breeds or types, most of which are named after the country or region where they are raised. For each breed or type, the chapter summarises: origin, distribution, population statistics if available, physical characteristics including some breed photos, adaptive and resilience features, typical production systems and production characteristics. The depth of discussion is different between breeds due to the differential availability of data or information. Sections 10.4, 10.5, 10.6 and 10.7 further considered donkey breeding and production systems in Africa, diversity and population structure, conservation and important roles that donkeys play in

10.1 Introduction

The African wild ass or wild donkey (*Equus asinus africanus*) is a wild member of the horse family, Equidae, and is considered an ancestor of the domestic donkey. Donkeys are commonly raised in developing countries, especially in rural communities, for their multiple roles. The male donkey is called a jack, the female a jenny or jennet and the young a foal. The donkey can survive under poor management and environmental conditions with unique characteristics (tough, obedient and docile), which allow women and children to handle them (Orhan et al. 2012; Yilmaz et al. 2012a). The donkey population in Africa constitutes about 70% of the African equine population (FAOSTAT 2024) and is mainly found in the arid and semi-arid areas, offering a reliable, environmentally friendly and renewable source of draught power to millions of poor communities. In terms of world head counts (FAOSTAT 2024), Africa ranks first in donkey production, estimated at 32,686,779 (63.24%), followed by Asia (12,391,888; 23.97%), Americas (6,499,519, 12.57%), and Europe (100,208; 0.19%), while Oceania is least with 8879 donkeys (0.02%). The donkey is among the predominant species (cattle, sheep, goat and camel) managed under large-scale extensive production systems (pastoral and transhumance), which underscores its importance in the lives of the African people (AU-IBAR 2019). See Chapter 2 for a detailed description of the livestock production systems and agro-ecological zones in Africa. Based on FAOSTAT (2024), the semi-arid areas of the continent, particularly East Africa, produce most (34.10%) of the donkeys, while the remaining 66% of production is shared among North Africa (29.89%), West Africa (22.96%), Central Africa (11.50%) and Southern Africa (1.54%). The populations of donkey have been fluctuating across the African continent over the last 5 years (Table 10.1) with less than 1% average annual increase (East, Central and West Africa) or decrease (North and Southern Africa).

The contributions of donkey to livelihoods are substantial and more complex than earlier understood and documented (Maggs et al. 2021). In terms of socio-economic and cultural importance, donkeys are renowned for the following: 1. They are highly treasured by their owners since they provide a pathway out of poverty. A study in Ghana where owners described donkeys as priceless (Maggs et al. 2021) showed that donkey ownership confers up to six different income benefits (accounting for about 30–60% of their income), including (1) income generated from renting out donkeys; 2. Donkey reduce the physical hard work of land ploughing; 3. They assist in domestic chores such as transportation of goods to and from the market, transportation of water from water points/streams and firewood, etc.; 4. Donkey help in transportation of people and goods and contribute to animating the weekly markets between villages (Sow et al. 2012); 5. Donkey is a source of milk and meat. Annual production of donkey meat in Burkina Faso was esti-

Table 10.1 Donkey populations by regions in Africa for the period 2018–2022 (FAOSTAT 2024)

	Donkey number by year					Average annual increase	
Region	2018	2019	2020	2021	2022	Number	%
Africa	31,299,133	31,714,794	33,128,431	32,866,771	32,686,779	346,911.50	0.04

mated at 800 tonnes in 2008 (Sow et al. 2012); and 6. There is an increasing demand for donkey skin, which is used for the production of a traditional Chinese medicine (ejiao), thereby threatening the global donkey population (Maggs et al. 2021).

Despite the fact that the donkey is important to the subsistence of many communities in the arid and semi-arid regions of most developing countries, they have received very limited or no attention from research and development agencies compared to other domesticated species. In a few African countries (Ethiopia, Nigeria, Cameroon, Algeria, Lesotho, etc.), phenotypic characterisation of indigenous donkey breeds has been reported (see Sect. 10.3). There is therefore an urgent need to intensify research efforts on donkey phenotypic and genetic characterisation, which will facilitate classification of donkey breeds/types and boost utilisation for improved productivity and conservation in Africa. This chapter presents an overview of donkey production in Africa with a focus on origins, history of introduction and dispersion, breeds/types and diversity, breeding and production systems, various uses, challenges encountered in the donkey enterprise and future perspectives.

10.2 Origin of the Domestic Donkey and Dispersion in Africa

The donkey, or ass, is a member of the equine family. The equine family includes the horse, mule, donkey and zebra. The domestic donkey is believed to originate from the African wild ass or African wild donkey (*Equus africanus)*. The domestic donkey (*Equus africanus)* is often regarded as the most neglected and least studied animal species in the world. However, the domestication of donkeys radically changed the ancient transport systems in Africa and Asia, allowing the overland movement of people and goods and influencing the organisation of the first cities and pastoral societies (Rossel et al. 2008). The original motive for domesticating the donkey is unknown, and it is not certain that it would necessarily reflect its common usage today as a means of transport for people and goods. It may have been domesticated for its meat and milk, with its use for portage a later development (Blench 2012).

The African wild ass or African wild donkey is a wild member of the horse family, Equidae, and considered the ancestor of the domestic donkey. It lived in the deserts and other arid areas of the Horn of Africa, Eritrea, Ethiopia and Somalia. Today, only seven species of equids remain, and many of them face some sort of risk or are threatened with extinction (IUCN 2022). The seven extant equid species are characterised by their rapid chromosomal divergence and recent speciation (Librado and Orlando 2021; Orlando et al. 2009). Of the seven living species of the genus Equus, only two wild species were domesticated, namely, the Botai wild horse (*Equus caballus*) and the African wild ass (*Equus africanus*) (Beja-Pereira et al. 2004; Kimura et al. 2011, 2013; Librado et al. 2021).

The reconstruction of the origin and spread of the domestic donkey was initially contentious due to the limited archaeological record of early donkeys (Kimura et al. 2013; Mitchell 2018). Archaeological evidence of donkeys was found in North Africa, from the Moroccan Atlas Mountains to Somalia in Eastern Africa, such as

at Egypt's El Omari (4800–4500 BCE) and Maadi (4000–3500 BCE), carvings on Libyan palettes depicting lines of walking animals (donkey, cattle and sheep) and archaeological remains in Abydos, Egypt (3200–3000 BCE) with suggestions of domestication in a region extending from the Northeastern Sahara, the Atbara River, the Nile Valley, and the Red Sea Hills of the Sahara Desert to Eritrea in the Horn of Africa (Rossel et al. 2008; Beja-Pereira et al. 2004; Kimura et al. 2011; Librado et al. 2021; Todd et al. 2022; Levtzion and Hopkins 1981). These narratives suggest that the donkey was domesticated in Africa by pastoralists to help with mobility and transportation of goods in the difficult landscape of the Sahara around 5000–7000 years ago BCE (Beja-Pereira et al. 2004; Mitchell 2018; Xia et al. 2019). Other evidence based on DNA sequence variation and patterns of mitochondrial DNA (Beja-Pereira et al. 2004; Todd et al. 2022; Wang et al. 2020) supports the African origins of the donkey. However, other regions outside of Africa are also proposed as alternative domestication centres, such as Ash Shuman in Yemen (ass remains dated to ~6500 BCE) and Mesopotamia (iconographic, textual, and zooarchaeological evidence dated to the fourth and third millennia BCE) (Todd et al. 2022).

The ancestors of the donkey are generally considered the two extant wild African ass subspecies (Nubian wild ass- *E. africanus africanus* and the Somali wild ass- *E. africanus somaliensis*) and the Asian wild half-asses (*E. hemiones* and *E. kiang*). Reports on mitochondrial DNA data from ancient archaeological and historic museum samples of modern-day donkeys revealed two distinct mtDNA haplogroups, Clade I and II, proposing the Nubian wild ass (*Equus africanus africanus*) as the ancestor of Clade I and either the extinct Atlas wild ass (*Equus africanus atlanticus*), which was found in North Africa, or an undescribed subspecies found outside of Africa as the ancestor of Clade II (Beja-Pereira et al. 2004; Kimura et al. 2011). Moreover, data on mtDNA control regions from both Asian wild half-asses and the two extant wild African ass subspecies (the Nubian wild ass, and the Somali wild ass) clearly eliminated the possibility of the Asiatic half-asses as progenitors of domestic donkeys (Beja-Pereira et al. 2004). While the Nubian wild ass was considered the ancestor of Clade I, the Somali wild ass had substantial mitochondrial divergence from the Nubian wild ass and domestic donkeys, raising new questions concerning the second ancestor for the donkey. With no distinct phylogeographic structure, information on wild ancestors and geographical origins for the domestic mitochondrial clades could not be obtained from the haplogroups. The results of Kimura and colleagues (2011), therefore, exposed the complexity of the domestication process with implications for whether a single maternally inherited marker could completely capture the ancestry of the domestic donkey. To resolve these controversies surrounding the origin and dispersal of domestic donkey, Todd and colleagues (2022) recently reconstructed a comprehensive genome panel of 207 modern and 31 ancient donkeys, as well as 15 wild equids, to clarify their domestication history, and found a strong phylogeographic structure in modern donkeys that supports a single domestication event in Africa ~5000 BCE. This was followed by further expansions on the continent and Eurasia and ultimately returning to Africa. The findings by Todd and colleagues (2022) validated early domestication in Africa that spread at an even rate into the Arabian Peninsula and Eurasia and flowed back into Nubia and Maghreb. Modern donkeys from the Horn of Africa and Kenya are considered to be descendants of the earliest donkeys. Modern donkeys in a phylogenetic reconstruction were grouped according to sampling locations into Clade A (African donkeys) and Clade B (mostly non-African donkeys) (Todd et al. 2022). Within Clade A, donkeys from the Horn of Africa (Ethiopia and Somalia) plus Kenya were separated from those from West Africa (Ghana, Mauritania, Nigeria and Senegal). Clade B also included donkeys from Nubia (Egypt and Sudan) that showed affinities to the Levant (Syria) and Anatolia (Turkey), as well as donkeys from Maghreb (Tunisia), with closer genetic closeness

to European sub-populations, suggesting gene flow into Africa from donkeys that were native to Anatolia and the Levant, but not to the Arabian Peninsula. The authors concluded that the domestication centre of modern-day donkeys is the Horn of Africa and Kenya in about 5000 BCE, followed by expansion in continental Africa and Eurasia and ultimate return to Africa (Todd et al. 2022). Figure 10.1 depicts this theory of the African centre of donkey domestication and spread to other parts of the world and back to Africa.

The spread of the domestic donkey out of its domestication centre can be divided into three key phases: before European contact, during European contact and the subsequent era. The study by Todd and colleagues (2022) narrowed the domestication of donkeys to a unique African location (~5000 BCE) and subsequently spread into Eurasia from ~2500 BCE, while Central and Eastern Asian sub-populations differentiated ~2000–1000 BCE. After early domestication, African donkeys further differentiated in the West and the Horn of Africa plus Kenya but also received streams of genetic ancestry from Western Europe as well as a region encompassing the Levant, Anatolia and Mesopotamia. Donkeys spread by land from farmer to farmer and slowly diffused during the first phase. For the second phase, donkeys were spread by carriage in ships during the colonial era, through projects, state institutions, and rapid diffusion of animals. Earlier information on the donkey in the West African Sahel from Arabic material described the region and referred to the donkey as already domesticated (Levtzion and Hopkins 1981; Lewicki 1974). The diffusion of the donkey in pre-European contact times seems to have been strictly by land, mostly across the Sahara (Fig. 10.1), spreading gradually from country to country. There is a reference to 'Muscat' donkeys in Tanzania in the 1950s (Mason and Maule 1960), describing light-coloured donkeys associated with the Arab people, which may have been brought from the Gulf region or from Egypt, where they have a long tradition of use. In the past, donkeys diffused principally from farmer to farmer or were sold by occupationally specialised pastoralists, as in West Africa. During the colonial era, donkeys were brought into Africa mostly by sea, which served as a means of inland transportation by colonial masters and draft power for agricultural purposes. However, in recent times, the spread of the donkey is through national agricultural programmes, aid agencies and acquisition by farmers to support agricultural work and transportation. Most importantly, the donkey has been recommended for traction in regions with light, sandy soils, and the industrial manufacture of axles for donkey carts is being made available to farmers to boost farming activities. The informal diffusion of donkeys continues even today. The clearing of the savannah forest South of the Sahel and the consequent decline in tsetse challenge have permitted donkeys to spread southwards. Donkeys can survive on low-quality diets and can find food in the peri-urban wastelands surrounding many African towns. With deforestation and land degradation leading to decreased biodiversity, donkeys can also feed on the shrubs that persist under these conditions (Blench 2012).

Although the species name of modern donkeys is commonly written as *Equus asinus*, recent evidence pointing to Africa as the centre of donkey domestication implies that *Equus africanus* is the correct nomenclature. The name *Equus asinus* was introduced by Asinus Linnaeus (1758), referring to donkey populations in Turkey (Eurasia), which as a subspecies of the African wild ancestor, is referred to as *Equus africanus* subsp. *asinus* (*https://www.gbif.org/species/113279747*). The scientific classification of the present-day domestic donkey is:

Kingdom	Animalia
Phylum	Chordata
Class	Mammalia
Order	Perissodactyla
Family	Equidae
Genus	Equus
Species	*E. africanus*
Subspecies	*Equus africanus* subsp. *asinus*

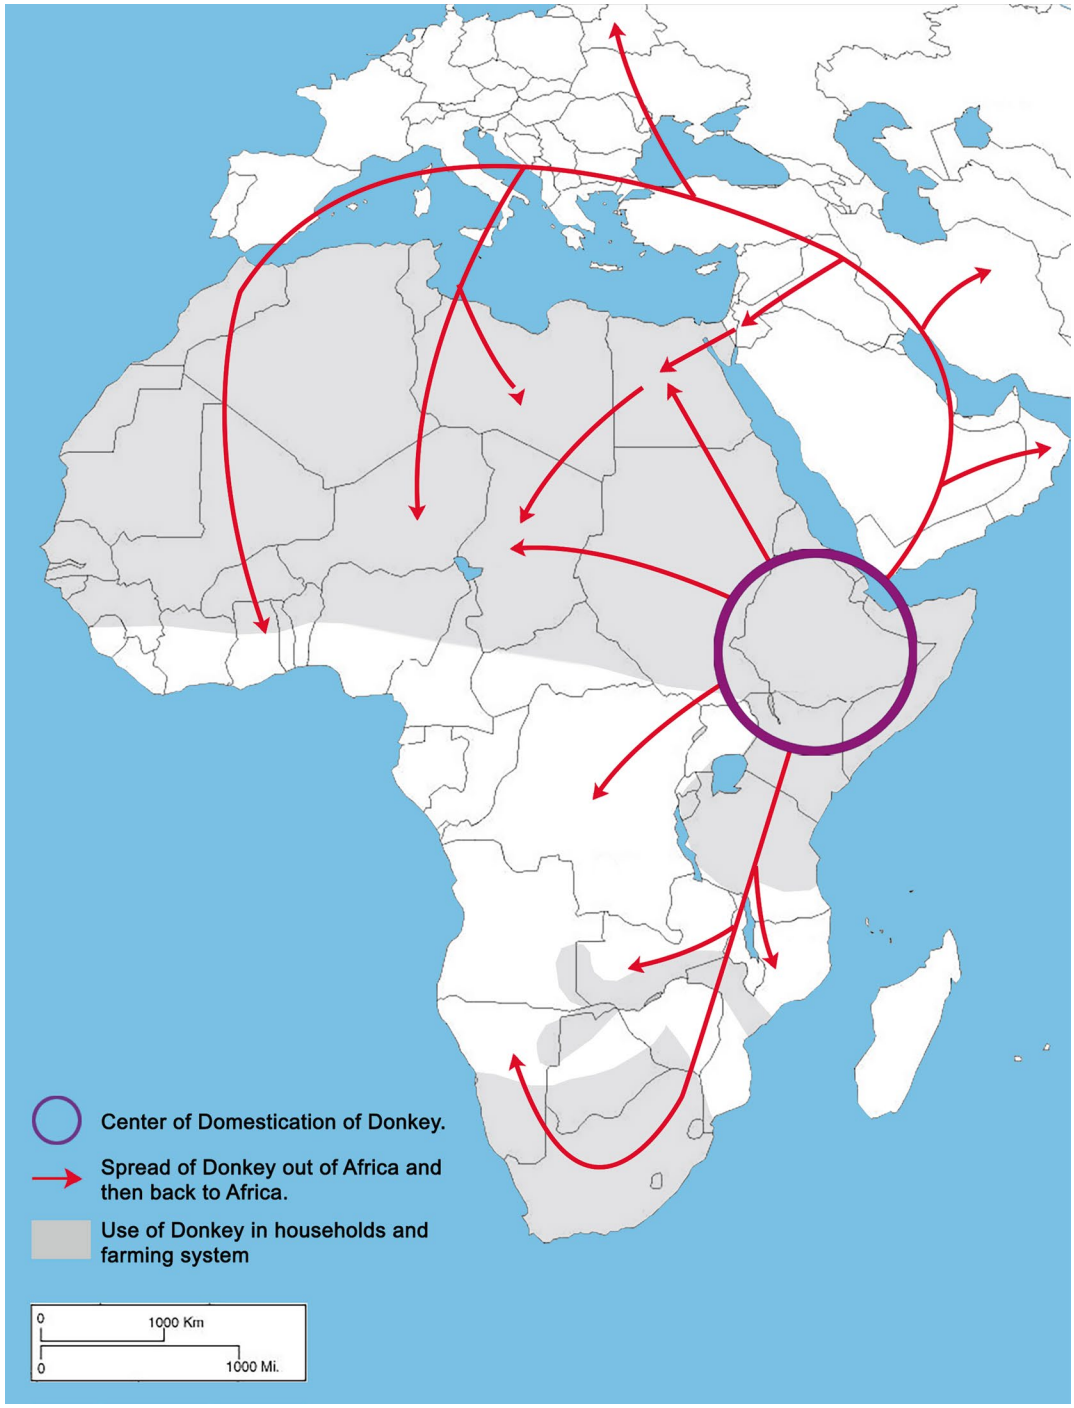

Fig. 10.1 Origin of domestic donkey and routes of dispersion in Africa, Asia and Europe

10.3 Donkey Breeds and Types in Africa

The donkey breeds of Africa are of different sizes and colours and have acquired versatile abilities to adapt to the increasingly changing and dry environments of the arid and semi-arid regions of Africa. In general, the donkey breeds of Africa possess the following characteristics: (1) The breeds vary in body size, a characteristic that helps them to adapt to limited feed resources and water, and high ambient temperatures of its diverse range of environments; (2) have ability to walk long distances and to navigate a wide range of difficult terrains and harsh environments such as sandy, rocky and mountainous terrains; (3) have ability to carry heavy loads and plough the soil, thus making them valuable assets to their owners; (4) they have a working life of about 12–15 years and bring profitable earnings to their owners; (5) they have a digestive system adapted to extract nutrients from poor quality feeds; (6) they have large ears that helps them to cool and regulate their body temperatures ensuring survival in very hot environments; (7) they have varied coat colours that helps in heat deflection and protection against predators; (8) they have ability to graze easily and throughout the day thus ensuring acquisition of available feed resources; (9) they have a loud bray for communication with other donkeys; (10) they are docile, friendly and easy to handle by women and children; and (11) they are a source of enhanced security and well-being to their owners.

10.3.1 Donkey Breeds and Types in West and Central Africa

Donkeys are more prevalent in the arid and semi-arid regions and mostly owned by pastoralists and settled farmers who use them as a source of traction power or means of transport. Four major types or breeds have been reported (Blench et al. 1992) based on coat colour in Nigeria. The names in Hausa are: Auraki (rust or red), Duni (dark brown to black), Fari (pale cream to white) and Idabari (grey to light-medium brown). Khaleel et al. (2020). categorised donkeys in Kano (Nigeria) into seven different coat colour types (Table 10.2), with the majority of individuals having light grey colour (30.6%). Multi-coloured donkeys having light brown with dark stripes, locally called L'âne du Miankala, are also widely distributed in Mali. Information on the presence of donkey is limited to a few countries within the two sub-regions, which include Burkina Faso, Côte d'Ivoire, Ghana, Mali, Mauritania, Niger, Nigeria, Senegal and Togo (West Africa); Cameroon, Chad and the Central African Republic within the Central African sub-region. The grey donkey is the most prominent breed or type among other colours, based on limited reports from several countries highlighted below.

Table 10.2 Distribution of donkey types in Nigeria based on coat colours

Colour	Hausa name	Percentage (%)
Light grey		30.6
Light Brown	Idabari	16.7
Dark brown	Duni	13.9
Dark grey		13.9
Black	Duni	11.1
White with brown	Idabari-fari	8.3
White	Fari	5.5

Source: Khaleel et al. (2020)

10.3.1.1 Idabari

Synonyms: Other names by which Idabari (grey or light-medium brown donkeys) are known in Africa include L'âne du Gourma, L'âne du Miankala, L'âne du Sahel, L'âne du Yatenga, Native of North Africa (Mali); Native of North Africa, Âne commun d'Afrique (Mauritania, Senegal); Anes, l'Ane Africaine (Niger, Togo), and L'Ane Africaine or RifaÏ (Chad).

Distribution and Population Statistics: Idabari are the most predominant among different colour variants in the West African sub-region, notably in Nigeria (Khaleel et al. 2020), Mali, Mauritania, Niger and Togo; as well as Cameroon (Nguekeng et al. 2017), Central African Republic and Chad within the Central African sub-region. Donkeys were widespread in Nigeria, but the number drastically reduced during the oil boom in the mid-1980s when they were being replaced by

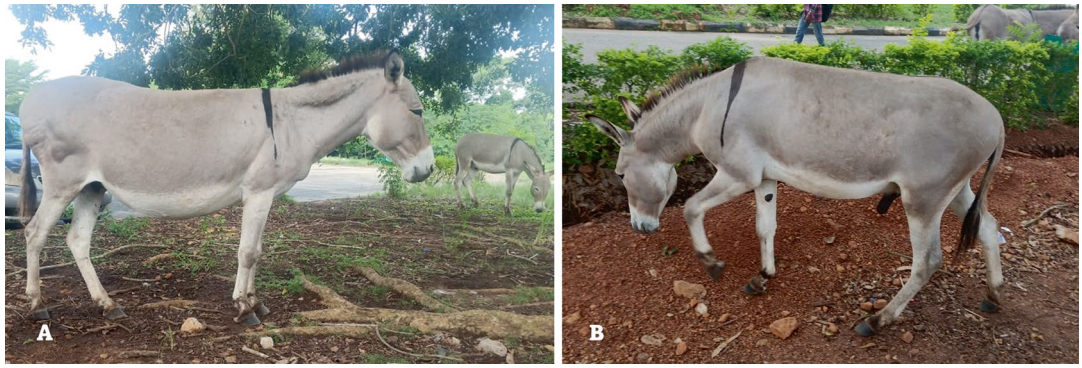

Fig. 10.2 Idabari jenny (**a**) and jack (**b**) at the Federal University of Agriculture, Abeokuta, Nigeria. (Photos by M.N. Bemji)

motorised transport (Blench et al. 1992). However, following economic depression, the demand for donkeys increased substantially. The populations of donkeys were estimated at 1,009,615 in Burkina Faso, with an annual growth rate of 2% (Sow et al. 2012); 250,000 for Native of North Africa and Âne commun d'Afrique (2006 census) in Mali and Mauritania; and 3086 (2006) in Togo (DAD-IS 2024). The donkeys in Chad were imported from Egypt in 1921. They are found in arid and semi-arid areas of Chad and the Sahel and are considered to be at risk, with a population size of 349,982 in 2000 (DAD-IS 2024). According to Ebangi and Vall (1998), the donkey population in Cameroon increased from 700 to 21,000 between 1978 and 1997.

Physical Characteristics: The donkeys within the sub-region are generally of small to medium size, with height at withers being 90 cm (males) and 110 cm (females) for donkeys in Chad. Data from grey and white donkey populations in Cameroon (Nguekeng et al. 2017) showed that average adult liveweight was 122.11 ± 1.24 kg. Females were heavier (124.72 ± 1.65 kg) than males (120.44 ± 1.79 kg). In an earlier study within the same region, the average liveweights of adult (6–13 years old) female and male donkeys were 132.5 ± 2.3 and 123.2 ± 2.1 kg (Ebangi and Vall 1998), respectively. The coat colour of Idabari is predominantly made up of shades of grey (94%) with a black band on the shoulder region (shoulder cross-stripe) and shades of white around the nostrils, the ventral regions and the inner portion of the legs (Fig. 10.2). A study from three localities (Bogo, Gazawa and Kaélé) in the Sudano-Sahelian Zone of Cameroon (Nguekeng et al. 2017) showed that donkeys had predominantly grey coat colour (80.02%) while those with white coat colour (Fari) (4.85%) were least represented, corroborating an earlier study by Ebanji and Vall (1998). The majority of the donkeys displayed the St. Andrew's cross (84.50%) and not zebra lines (76.20%). For morphological characteristics, estimates were 98.05 ± 6.88 cm (height at withers), 108.31 ± 6.82 cm (thoracic), 101.37 ± 13.07 cm (trunk length), 40.47 ± 8.79 cm (neck length), 25.09 ± 1.24 cm (right ear length) and 25.43 ± 1.07 cm for length of the left ear. Data on phenotypic characterisation of donkeys in Nigeria with different colours (Red, Black, White, Brown and Brown-white) by John et al. (2017). showed that majority of adult donkeys had smooth and short hair type (90%), brown coat colour (88.57%), thick skin type (86.07%), solid coat colour pattern (99.64%), pendent tail shape (50.36%), black eye colour (94.64%) and straight head profile (92.86%). Most of the distributions were similar for young donkeys. Donkeys in northwestern Nigeria were mostly of solid coat colour pattern, with short and smooth hair type, brown coat colour, thick skin type, pendent tail shape, black eye colour and straight head profile.

Adaptive and Resilience Features: Donkeys are monogastric herbivores; they eat a wide variety of feeds (roughages) and utilise cellulose and

hemicellulose efficiently; hence, they are easy to manage and can practically survive on poor-quality feeds (Aganga et al. 2000). They thrive under adverse climatic conditions and can tolerate considerable heat and dehydration (Smith and Pearson 2005). They also tolerate some tropical diseases and parasites.

Typical Production Systems and Production Characteristics: Fulbe pastoralists mainly use donkeys as pack animals as they migrate from one grazing area to another. During transhumance, donkeys carry tents, camp utensils, children, women, old people, poultry in cages, lambs and kids to new locations. Donkeys are tethered at night, but during the day, they are untethered and allowed to scavenge for grazing in the vicinity of the camp (Blench et al. 1992). In the Sudano-Sahelian zone of Cameroon, the donkeys usually fend for themselves on open natural pastures during the dry season, with little or no health care. During the farming period (rainy season), they are brought back to graze around the houses, and little health care is offered. Varying amounts of sorghum grains and cotton seed cake are given as feed supplements (Ebangi and Vall 1998). At the National Animal Production Research Institute, Zaria, Nigeria, donkeys are semi-intensively managed with grazing being supplemented with straw and concentrates (Sheriff Yusuf et al. 2020).

Reproductive parameters of donkeys reported in Nigeria include the mean age of breeding (96 ± 29 SD months), mean age at first foaling (57 ± 17 SD months), foaling interval (26 months), and mean number of previous parities (2.1) (Blench et al. 1992). Length of the oestrous cycle is about 24 days, while the length of oestrus is 6–7 days, with oestrus occurring throughout the year in tropical climates (Fielding 1988). Gestation period is about 1 year. Body condition of breeding females may not depreciate to the extent of completely inhibiting fertility, with the conception pattern reflecting the ability of donkeys to thrive on the poorest of diets. Free mating of donkeys is allowed in Nigeria when they are herded, but there is restricted access of females to males when jennies are used for work. A mortality rate of 7% was reported in Nigeria (Blench et al. 1992). Most males are sold soon after weaning, with few kept for breeding and work. The pastoral system in Niger and the rural system in Nigeria have a similar donkey herd structure, with 30% males, 70% females and about 50% breeding females, while the urban system in Mali has more males (85%), fewer females (15%) and breeding females (11%).

Local donkeys are highly regarded in Niger and the extreme north of Togo (in the savanna area), and they play very prominent roles such as: animal therapy, draught power, fuel (manure), meat, pack/baggage, pelt or fur, skin/hides, transport, vegetation management, waste recycling of non-human edible feed, weed control and biomass residue management, dressage, racing, cultural and religious ceremonies, and riding (children). Donkey racing is found countrywide in Mali.

10.3.1.2 Auraki, Duni and Fari Donkey Types

The Auraki (rust or red), Duni (dark brown to black; Fig. 10.3), and Fari (pale cream to white; Fig. 10.4) donkey types constitute the minority in the countries of the West and Central African sub-regions, where limited information has been provided on characterisation. Apart from reports on separate estimates for their frequencies in mixed populations (see Sect. 10.3.1), they were not separated from their Idabari counterparts in the analysis for quantitative variables. More phenotypic and molecular characterisations are required to establish the differences among various donkey types for improved utilisation and conservation.

10.3.2 Donkey Breeds and Types in North Africa

The North African sub-region is the second largest producer (29.89%) of donkeys in Africa (Table 10.1). Scanty information on the donkey is limited to a few countries (Algeria, Egypt, Libya, Morocco, Tunisia and Sudan), in which the breeds are discussed.

Fig. 10.3 Dunni donkeys at Zaria, Nigeria. (**a**) brown, and (**b**) black types. (Photo by DR. E. M. Ibeagha-Awemu)

10.3.2.1 Algerian Ass

Synonyms: The Algerian ass is also known as the Algerian Ardi or the African donkey.

Distribution and Population Statistics: The breed is native to Algeria. A review (Hannani et al. 2020) showed that the donkey population in Algeria reduced from 315,000 in 1961 to 136,000 in 2013.

Physical Characteristics: The Algerian Ass is medium in size with an average wither height of about 105.3 cm for donkeys in the Kabylie area of Algeria (Ayad et al. 2019), 110.5 cm for extreme eastern Algerian domestic donkey (Hannani et al. 2020), while estimates of 121.92 cm at the shoulder for males and 111.76 cm for females have also been reported (GO 2024). Body weights estimated from linear body measurements using two different equations were 144.3 ± 23.9 and 171.5 ± 28.8 kg, respectively (Ayad et al. 2019). The donkeys have a short, thick coat which varies in colour (grey, black and white). Frequencies for colour variants were estimated at 59.5% for various shades of brown, 27% grey and 13.5% black in the Kabylie area of Algeria (Ayad et al. 2019). In another study, bay and greyish colours were dominant, with a prevalence of 61.5% and 38.5% respectively, for extreme eastern Algerian domestic donkey (Hannani et al. 2020). The head, nose and eyes contour colours were mainly grey with 52.3%, 58.5% and 50.8% respectively. The donkeys were longilinear, or a rectilinear profile, compact with a massive body. Linear body measurements reported by Ayad et al. (2019). were: head length (46.3 cm), ear length (23.6 cm), neck length (48.9 cm), chest width (24.7 cm), back length (61.7 cm), body length (109.6 cm), hips width (32.5 cm), umbilical circumference (142.8 cm), back height (107.8 cm), height at the rump (108.7 cm), thoracic circumference

Fig. 10.5 Egyptian donkey. (Source Wikipedia: photo Jerome Bon by https://en.wikipedia.org/wiki/List_of_donkey_breeds#/media/File:Egyptian_donkey_(2428011421).jpg, CC-BY-2.0 license)

(110.2 cm), chest depth (49.6 cm), front leg length (77.2 cm), cannon circumference (14.8 cm), cannon length (20 cm) and cannon height (30.3 cm).

Adaptive and Resilience Features: The Algerian donkey is hardy and well adapted to the harsh desert climate of North Africa. It is well known for its strength and endurance and is used for different purposes, such as transportation, farming and as a pack animal.

Production Characteristics: The animals are good for meat production (Hannani et al. 2020), milk, and as a source of work for transportation, ploughing and other farming activities.

10.3.2.2 Egyptian

Synonyms: Baladi or white Egyptian of Lower Egypt; Hassawi (widespread); and Saidi (White Egyptian of Upper Egypt) (Yilmaz et al. 2012b; Orhan et al. 2012). Donkeys in ancient Egypt were called Aa-hemet or Eeyore in Hieroglyphic (Attia 2017).

Distribution and Population Statistics: The Egypt Baladi is found in Lower Egypt (northern Egypt), Hassawi is distributed countrywide, while Saidi is found in Upper Egypt (southern Egypt). Based on a review (Attia 2017), there are approximately three million working donkeys in Egypt. Despite their importance to local communities, the Baladi donkey population is facing threats from habitat loss, competition from other livestock species, and crossbreeding with other donkey breeds.

Physical Characteristics: Baladi donkeys (Fig. 10.5) are typically medium to large in size, with height ranging from 122 to 142.25 cm (Yilmaz et al. 2012b; Orhan et al. 2012); 142.24 to 152.4 cm at the shoulder (GO 2024). Donkeys in Egypt generally vary in size depending on breed, with body weights ranging between 80 and 480 kg and height at withers between 79 and 160 cm (Attia 2017). The donkey in ancient Egypt was about 1.2 metres high and had a body weight of about 272.16 kg, much larger than the modern donkey. There are variations in Baladi coat colour (white, grey, black and brown).

Adaptive and Resilience Features: The Egyptian Baladi donkey has renowned strength and endurance and is versatile due to its muscular build and strong legs. It is also known for its

Fig. 10.6 Libyan donkey. (Photo Source: Wikipedia and available at https://en.wikipedia.org/wiki/List_of_donkey_breeds#/media/File:Donkey_in_Wasita_Libya.jpg, CC-BY-4.0 license)

smooth gait and good temperaments and can adapt to a wide range of environments and uses (GO 2024).

Typical Production Systems and Production Characteristics: Donkeys are allowed to roam in herds, watched over by a herdsman. A jenny has a gestation period of about 12 months and gives birth to a single foal (twin births are rare). The donkey was the most important transporter of loads and people in ancient Egypt. It is also used for agriculture and as pack animals. Working donkeys in the poorest countries have a life expectancy of 12–15 years and may live between 30 and 50 years in wealthy countries (Attia 2017).

10.3.2.3 Libyan

Distribution: The Libyan donkey breed is native to Libya.

Physical Characteristics: Libyan donkey is a medium-sized breed, with height at withers ranging from 121.92 to 142.24 cm and body weight between 181.44 and 249.48 kg (GO 2024). The smaller variety is bay with a pale belly, and the larger variety has a dark bay or grey coat. They have a variety of colours, including grey, black, and brown (Fig. 10.6).

Adaptive and Resilience Features: The Libyan donkey is highly versatile with a strong and sturdy body, hard-working and intelligent. It is also well adapted to different terrains and climates, making it a preferred choice for farmers in the region (GO 2024).

Production Characteristics: The breed is used for a variety of tasks, including ploughing fields, carrying heavy loads, and serving as a pack animal. It is also considered an important part of Libya's cultural heritage.

10.3.2.4 Tunisian

Synonym: Anne Tunisien.

Distribution and Population Statistics: The Tunisian donkey is native to Tunisia and the surrounding regions. The population estimated at 240,200 in 2021 is not considered to be at risk (DAD-IS 2024).

Physical Characteristics: The Tunisian donkey is a medium-sized breed with height at withers estimated between 121.92 and 142.24 cm (GO 2024). It has a distinctive appearance with a short, rounded head and large, floppy ears (Fig. 10.7). The build is sturdy and muscular, with well-defined withers. Coat colour varies, including grey, black, and brown.

Adaptive and Resilience Features: It is very hardy, intelligent and has a good temperament. With regards to personality, the donkey breed is very friendly and has a curious nature, eager to please their owner and easy to handle and train

Fig. 10.7 Tunisian. (Source: Wikipedia and available at https://en.wikipedia.org/wiki/List_of_donkey_breeds#/media/File:Barrage_bni_mtir_456789_13.JPG, CC-BY-3.0 license/)

Fig. 10.8 Moroccan. (Source: Wikipedia, photo by Dale Harvey and available at https://en.wikipedia.org/wiki/List_of_donkey_breeds#/media/File:Tamraght-daleharvey-10-donkey.jpg, CC-BY-2.0 license)

(GO 2024). It can adapt to a variety of environments, making it well-suited for work in a range of conditions in arid and semi-arid regions.

Production Characteristics: Tunisian donkey is well-suited for work as pack animals and for transportation. Despite the increasing use of modern machinery and transportation in recent years, the Tunisian donkey still plays a critical role in the daily lives of many rural communities in the region (GO 2024).

10.3.2.5 Moroccan

Synonyms: The Barb or the Atlas donkey.

Distribution: The breed is native to Morocco.

Physical Characteristics: The Moroccan donkey is a medium-sized breed with height at withers estimated between 121.92 and 142.24 cm and body weight between 272.16 and 362.87 kg (GO 2024). It has a variety of colours, including grey, black, and brown (Fig. 10.8).

Adaptive and Resilience Features: The Moroccan donkey is very strong with a sturdy build, versatile, hard-working and patient in nature. It is well adapted to different terrains and climates, hence, a preferred choice for farmers in the region (GO 2024).

Production Characteristics: The breed does a variety of tasks (carrying heavy loads, ploughing fields and serving as a companion animal), as

Fig. 10.9 Kassala donkey carrying grains from a market in Keren, Eritrea. (Source: Wikipedia- photo by David Standley and available at https://en.wikipedia.org/wiki/List_of_donkey_breeds#/media/File:Donkey_Transport_(8383370559).jpg, CC-BY-2.0 license)

well as an important part of Morocco's cultural heritage.

10.3.2.6 Dongola

Synonym: Dongolawi.

Distribution and Population Statistics: Dongola donkey is found in the northern regions of Sudan, including the Dongola region for which the breed is named. The population was estimated at 175,004 in 2020 (DAD-IS 2024). Despite its reputation in local communities, the population is facing threats from habitat loss and competition from other livestock species, thereby necessitating conservation efforts to preserve the breed.

Physical Characteristics: The breed is medium to large in size (larger than the Sudanese Pack), with height at withers ranging from 142.24 to 152.4 cm (GO 2024). Coat colour is variable, including black, dark brown or reddish-grey, occasionally pale grey or white with a white belly, muzzle and internal side of the thighs and arms.

Adaptive and Resilience Features: The Dongola donkey breed is noted for its strength and endurance, making it suitable for hot and arid environments. It has a muscular build and strong legs and is also renowned for its smooth gait and good temperament.

Production Characteristics: Dongola is highly appreciated in the region for its use as a pack animal and for transportation.

10.3.2.7 Kassala

Distribution: It is a breed of donkey found in the Kassala region of Sudan.

Physical Characteristics: The breed (Fig. 10.9) is medium size, with height at withers ranging from 121.92 to 142.2 cm and weighing between 181.44 and 249.48 kg (GO 2024). Coat colour is variable, including black, grey and brown.

Adaptive and Resilience Features: Kassala is known for its strong and sturdy body, endurance, versatility and high adaptability to different terrains and climates. It is hard-working and intelligent in nature.

Production Characteristics: Kassala is used for a variety of tasks, including ploughing fields, carrying heavy loads, and serving as a pack animal. It is also an important part of Sudan's cultural heritage.

10.3.2.8 Sennar

Distribution: The breed is commonly found in the Sennar region of Sudan.

Physical Characteristics: The breed is medium to large in size, has a sturdy build, strong

Fig. 10.10 Sudanese Pack. (Source: Wikipedia- photo by David Haberlah and available at https://en.wikipedia.org/wiki/List_of_donkey_breeds#/media/File:Donkey_carrying_Rahal_basket.jpg, CC BY-SA 3.0 license)

legs, with muscular and well-defined withers. It has a distinctive appearance, with a long sloping back, long legs, and large floppy ears. Coat colour varies, including grey, black, brown and white (DAD-IS 2024).

Adaptive and Resilience Features: The breed is very hardy and can adapt to harsh environments, making it well-suited for work in the hot, arid conditions of the Sennar region.

Production Characteristics: Sennar donkey is mainly used for ploughing fields, carrying heavy loads, and for milk and meat (DAD-IS 2024).

10.3.2.9 Sudanese Pack

The Sudanese Pack (Fig. 10.10) is a domestic donkey breed that is native to Northern Sudan. The breed is considered to be at risk, with an estimated population of 7609 in 2018 (DAD-IS 2024).

The Toposa donkey is found in Southeastern Sudan and the surrounding regions. It is not considered to be at risk, with a population of 570,664 in 2020 (DAD-IS 2024). In terms of physical characteristics, adaptive/resilience features and production characteristics, both breeds (Sudanese Pack and Toposa) are similar to the Tunisian donkey (see Sect. 10.3.2.4).

10.3.2.10 Sudanese Riding

Synonyms: Riffawi, Shindawi Riding Ass.

The Sudanese riding donkey has various subtypes or sub-breeds found in northern Sudan and northwestern Eritrea. They include: 1. Atabai, which is medium in size and has a height at the withers estimated at 102–112 cm, with varying coat colours (grey, white, reddish or dark brown, often without a cross); 2. Kassal is larger and has a reddish coat with a cross; 3. Massawa is almost white (Yilmaz et al. 2012b; Orhan et al. 2012). They are locally adapted and not at risk, with a population of 4,139,217 in 2020 (DAD-IS 2024); 4. Etbai (Elgash) is a smaller variety of Sudanese Riding found in the Bija Tribal Country, the Red Sea Mountains and the coastal area, north of Port Sudan in northwestern Sudan. The coat colour is grey with black or dark bilateral stripes running vertically from the wither to the tip of the shoulder. With regard to special qualities, Etbai is reported to be a trotter with a difficult character. The population was estimated at 1,133,719 in 2020 (DAD-IS 2024).

10.3.3 Donkey Breeds and Types in East Africa

The East African region possesses the largest donkey population on the African continent (Table 10.1), and in particular, Ethiopia has the largest population of donkeys in the world

(10.79 M, 10.02 M and 9.93 M heads in 2020, 2021 and 2022, respectively), while Sudan recorded the second largest populations in 2020 (7.63 M heads), 2021 (7.64 M heads) and 2022 (7.65 M heads) (FAOSTAT 2024). Ethiopia's strategic location in the Horn of Africa, which serves as a possible domestication centre as well as a major point of entry, and its ecological attributes are thought to have a major influence on its donkey populations in terms of number, geographical distribution, conformational differences, coat colour patterns and body sizes. While the donkey is amongst the most neglected livestock species on the African continent, the Ethiopian donkeys have received the most research attention (Kefena et al. 2011; Getachew et al. 2023; Wassie et al. 2023; Geiger et al. 2023; Eriso et al. 2023; Hassen et al. 2022; Kefena et al. 2021; Geiger et al. 2020), with several breeds reported: Abyssinian, Afar, Hararghe, Ogaden, Omo, Hamer and Sinnar. Other donkey breeds found in East Africa are Somali, Dongolawi, Maasai and Muscat. The donkeys of East Africa play important economic roles. They are mostly exploited for draught power and transport; they are prominent in festivals and entertainment and used in ceremonies such as gifts during weddings and food at funerals (Geiger et al. 2020, 2023; Admassu and Shiferaw 2011; Asteraye et al. 2024; Geiger and Hovorka 2015).

Donkey ownership has been reported to improve household income and livelihoods (Admassu and Shiferaw 2011; Asteraye et al. 2024; Curran and Smith 2005). In particular, ownership of a working-donkey is a key aspect of women empowerment through assistance with daily work burden (donkey used to fetch water; collect firewood for home use and sale; transport farm produce; transport grain to the mill house; transport items purchased at market back to the household, and till the fields, etc.) and improved economic status and standing.

In the peri-urban and urban areas of Ethiopia, working donkeys are common among youths, who use them for income generation by offering merchandise transportation services.

10.3.3.1 Abyssinian

Synonym: Ethiopian.

Distribution: The Abyssinian is widely distributed throughout Ethiopia, mostly along both sides of the Ethiopian highlands and in South Africa.

Physical Characteristics: Abyssinian is characterised by a small body size or dwarf, predominantly brown, occasionally chestnut-brown, slate-grey and hairy, has the primitive equine stripes with a clear dorsal stripe along the backline from the poll area to the tail and a shoulder stripe that runs across the withers area to make a cross; its ventral side, muzzle and nostril points are white in colour (Fig. 10.11). They are hardy and heavily working animals. Height at withers is 94 cm for both males and females.

Adaptive and Resilience Features: Abyssinian is a compact animal shown to be morphologically distinct from other donkey populations in Ethiopia (Kefena et al. 2011). The small body size is probably an adaptation to the highland ecology of its predominant habitat. Its main uses include draught power, carting, manure (fuel) and transport. It is also important for habitat provision and biodiversity transport through pollination and seed dispersal, weed control and biomass residue management. The gestation period of the Abyssinian ranges from 11 to 13 months, with a lifespan of 30–40 years. The composition of Abyssinian milk is closer to that of human breast milk in its protein, lactose, vitamin C, zinc, pH and density contents, while its calcium, iron and magnesium contents are higher than those of human breast milk (Tadesse et al. 2014).

10.3.3.2 Sinnar

Distribution: Sinnar's geographical niche is the northwestern lowlands along the Ethio-Sudanese border (from Humera to Assosa).

Physical Characteristics: Sinnar is the most peculiar donkey in Ethiopia with unique morphological characteristics. It is considered the tallest of the Ethiopian donkey breeds, with height at withers of 100–114 cm; average matured body weight of 126 kg for males and 129 kg for females (Kefena

Fig. 10.11 Abyssinian donkeys grazing (**a**), slate-grey Abyssinian adult donkey (**b**), and chestnut-brown Abyssinian jenny and foal (**c**). (Photos by Dr. E. Kefena, Agricultural Transformation Institute, Ethiopia)

et al. 2011; Mustefa et al. 2020). Sinnar has variable coat colours such as white, black, fawn, leopard and brown, with white and leopard coat colours being the most common, and most have white abdominal colour (Fig. 10.12). The leopard coat-coloured Sinnars have a ridge on their ribs. Morphologically, it is the second most distinct donkey breed in Ethiopia (Kefena et al. 2011).

Adaptive and Resilience Features: Sinnar is well adapted to the desert region of the country. It finds use as a working animal (draught power), carting, manure (fuel), transport and riding. It preserves biodiversity through seed dispersal and weed control. Sinnar jack, with its unique and peculiar phenotypic characteristics, is used by mule breeders to produce mules that command a premium price in Ethiopia (Kefena et al. 2011).

10.3.3.3 Afar

Distribution: Afar is mostly found in the Afar Plain as well as neighbouring western Hararghe mid and lowlands of Ethiopia.

Physical Characteristics: Afar has varied coat colours, including grey, greyish-red and light-red animals (Fig. 10.13). Leg stripes are common (Fig. 10.13b). Height at withers is 104 cm (Kefena et al. 2011). Afar is used to a small extent for draft power and manure (fuel). Its main use is in biodiversity maintenance through weed control, pollination and seed dispersal, and biomass residue management (Fig. 10.13a). Morphologically, Afar, Harar and Ogaden are very similar (Kefena et al. 2011).

Adaptive and Resilience Features: Afar is a free-ranging animal and is less used for work.

Fig. 10.12 Sinnar donkeys displaying different coat colours: (**a**) white, (**b**) brown, and (**c**) fawn. (Photos by Dr. E. Kefena, Agricultural Transformation Institute, Ethiopia)

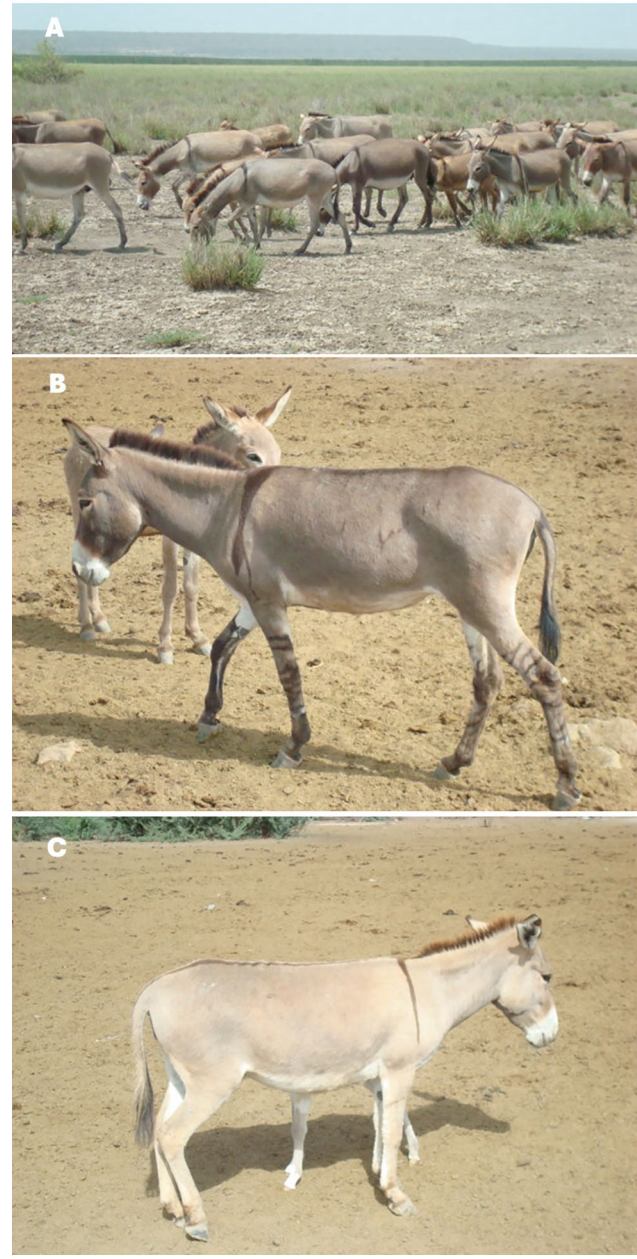

Fig. 10.13 A herd or drove of Afar donkeys (**a**) and Afar Jenny and foal (**b**, **c**). (Photos by Dr. E. Kefena, Agricultural Transformation Institute, Ethiopia)

10.3.3.4 Hararghe

Distribution: It is found in the Oromia/Hararghe highlands of Eastern Ethiopia.

Physical Characteristics: Hararghe has varied coat colours, with common colours being grey and brown; leg strips are common. It is a heavy working animal. Other functions include carting, draught power, manure (fuel), transport and biodiversity maintenance. Height at withers is 10.3 cm (Kefena et al. 2011).

Adaptive and Resilience Features: Hararghe is adapted to the Hararghe highland and shares phenotypic similarity with both Ogaden lowland and Afar donkey populations, but is obviously distinct morphologically (Kefena et al. 2011).

10.3.3.5 Ogaden

Distribution: Ogaden is widely distributed in the pastoral and agro-pastoral areas in the Somali Regional State (Somali/Ogaden plain) of Ethiopia.

Physical Characteristics: The coat colour is mostly grey and greyish red, and leg stripes are found in some individuals. Ogaden is used for carting, manure (fuel), weed control and biodiversity maintenance.

Adaptive and Resilience Features: Ogaden is a heavily built animal and is relatively used for work.

10.3.3.6 Omo

Distribution: Omo is predominantly found in the South Omo pastoral lowlands around Lake Turkana and Hamerin, Gnyangatom and Dasenech districts in Southern Ethiopia.

Physical Characteristics: This breed is peculiar as it has predominantly spotted dark-brown, fawn and light grey with shiny skin (Fig. 10.14). The fawn coat-coloured donkeys are mostly found in Hammer, Benatsemay and Dasenect districts (Getachew et al. 2023). It is a source of manure (fuel) and it maintains biodiversity through pollination, seed dispersal, and weed control. Omo served as a source of proteins for some tribal groups, and in recent times, served occasionally as a food source. Mean height at withers range from 104 to 110 cm (Kefena et al. 2011; Getachew et al. 2023).

Adaptive and Resilience Features: Omo is a fatty and heavily built donkey. It is free-ranging and is less used for work.

10.3.3.7 Maasai

Distribution and Population Statistics: Synonym: Masai. The Maasai donkey is found in the pastoral areas of southern Kenya and northern Tanzania and is reared by the Maasai pastoralists. In 2018, its population was estimated at about 600,000 in Tanzania, so the breed is not at risk.

Physical Characteristics: The Maasai donkey is a small animal with an average body weight of about 110 kg. It has a greyish-brownish (grey-dun) colour. The ventral side of the body, muzzle and nostril points are white, and it has the traditional equine dorsal stripe line from the poll area to the tail (Fig. 10.15). The average body measurements of Maasai donkeys were estimated at 156 kg (body weight), 100 cm (height at withers), 113 cm (body length) and 114 cm (heart girth) (Gichure et al. 2020a). It is mainly used by Maasai women to transport goods to the market and for draught power. It is not used as a food source by the traditional Maasai community. The Maasai is a valuable asset for semi-nomadic communities who depend on the donkey to transport movable goods to a new location. Culturally, it is used for racing and as a touristic attraction (such as donkey riding).

Adaptive and Resilience Features: The Maasai is well adapted to the Maasai system of free-range grazing.

10.3.3.8 Somali

Distribution and Population Statistics: The Somali donkey is native to the Horn of Africa, especially modern-day Somalia, northern Kenya, Djibouti and Yemen. Its population is declining, and it is considered an 'at risk breed'.

Physical Characteristics: Somali donkey is a small to medium-sized animal, with the withers height from 100 to 120 cm. It is slender and agile built, with long, slim legs, long, slender neck and large, floppy ears (Fig. 10.16). Its coat colour is in a variety of shades, including grey, brown, black and white. For centuries, the Somali donkey has been used for transportation, ploughing and herding. Because of its agility, speed, and endurance, the Somali is used as a riding and pack animal. Culturally, it is used for racing and for tourism as a riding animal.

Adaptive and Resilience Features: The Somali donkey is agile, runs fast and endures heavy loads and long distances. It is well adapted to the arid conditions of Somalia.

10.3.3.9 Somali Wild Ass

Distribution and Population Statistics: The Somali wild ass, *Equus africanus somaliensis*, is a variety of the African Wild Ass (the other variety is the Nubian wild ass). It is the smallest of the wild equids, a group made up of horses, asses and zebras. The Somali wild ass is found in

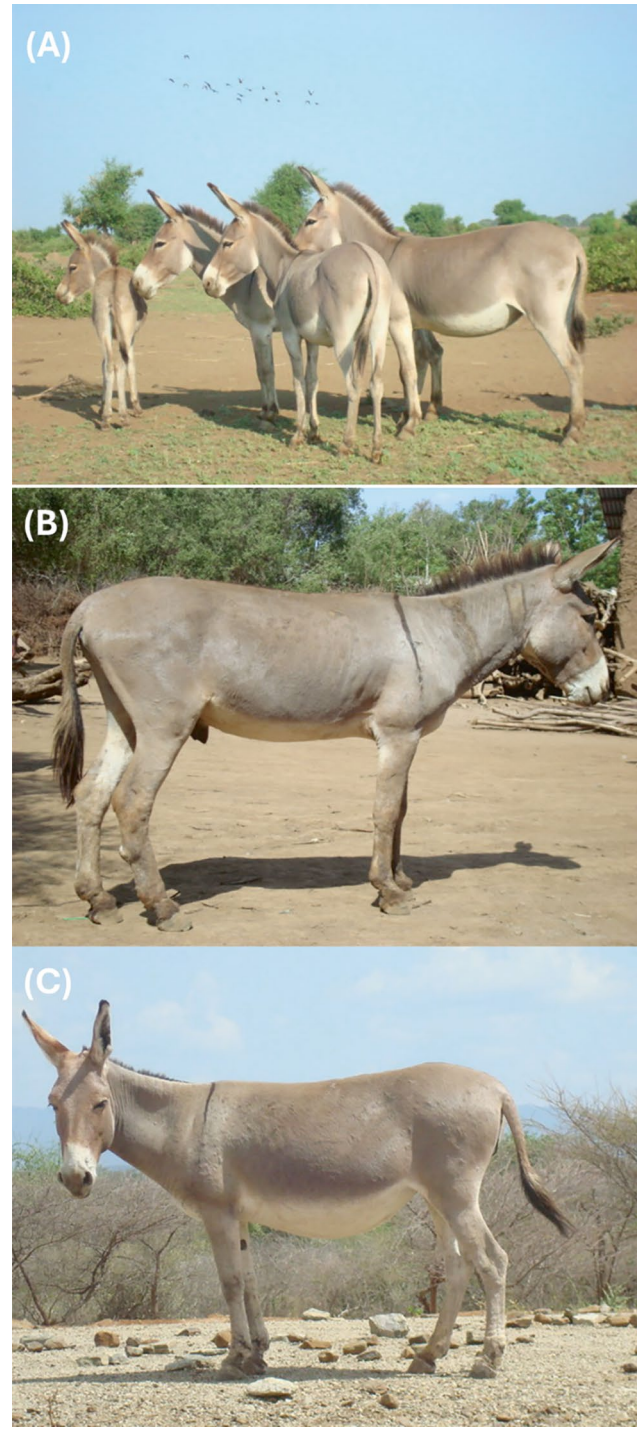

Fig. 10.14 A herd or drove of Omo donkeys (**a**) and fawn-coloured Omo jack (**b**) and jenny (**c**). (Photos by Dr. E. Kefena, Agricultural Transformation Institute, Ethiopia)

Somalia, the Afar region of Ethiopia, and the southern Red Sea region of Eritrea and Djibouti. It is a sleek, graceful and majestic animal that differs from the horse and zebra by its small size, larger ears, stiff mane, tufted tail and louder bray. Domesticated donkeys descended from the Somali and Nubian wild asses, as their images have been found painted in caves by ancient peo-

Fig. 10.15 A Maasai donkey (Source: Wikipedia. Photo by Daryona, https://commons.wikimedia.org/w/index.php?curid=10558134, CC BY-SA 3.0)

Fig. 10.16 A Somali donkey. (Photo by Dr. E. Kefena, Agricultural Transformation Institute, Ethiopia)

ple of North Africa (https://animals.sandiegozoo.org/animals/somali-wild-ass). Today, a few hundred animals are found in zoos in many countries, such as San Diego Zoo (California, USA), Franklin Park Zoo (Boston, Massachusetts, USA), Dallas Zoo (Texas, USA), St. Louis Zoo (Missouri, USA).

A population of 300 heads was reported in Somalia in 2006 (DAD-IS 2024) and likely less than 1000 Somali wild asses are found in the wild. Thus, it has been listed in the Red List of endangered species by the International Union for Conservation of Nature (https://www.iucn.org/), meaning that it is critically endangered and face the risk of extinction.

Physical Characteristics: The Somali wild ass has a reddish-grey coat, white on the ventral side of the body, muzzle and nostril points, a black-

Fig. 10.17 Two Somali Wild Asses (*Equus africanus somaliensis*) in Marwell Zoo, Hampshire, UK. (Source: Wikipedia-photo by Chris Keating, CC BY-SA 3.0, https://commons.wikimedia.org/w/index.php?curid=15354236)

and-grey upright (spiky) mane, and unique black and white stripes on their legs like their zebra relative (Fig. 10.17). In fact, it is the only donkey type with striped legs. It seldom possesses a dorsal stripe and shoulder cross-stripe common to most donkey breeds. It also has small, narrow hooves that facilitate fast and safe movement through its rocky habitat. The average height at withers for adults ranges from 120 to 150 cm, and the average adult weight is 270 kg. The gestation length is 11–12 months, and the birth weight of foals ranges from 20 to 25 kg.

Adaptive and Resilience Features: Somali wild ass is built to survive conditions of extreme heat, extreme high temperatures and very little water. Its large ears help with heat dissipation and to pick up sounds. The Somali wild ass feeds on arid and semi-arid scrubs, grass, bark and tough desert plants. Its habitat is hilly and stony desert lands.

10.3.3.10 Muscat

Distribution: The Muscat donkey is found in Tanzania and the Sebei and Karamoja regions of Uganda. It is believed to have descended from the Egyptian or Arabian donkeys.

Physical Characteristics: Visibly, the Muscat is larger and paler than the Maasai donkey (Fig. 10.18). Its main use is for draught power, transport, riding by children and as pack animals. It is small to medium-sized in build (compact and sturdy). Its appearance is distinctive with long ears and a convex profile. The coat colour is varied, including grey, black and brown. They are of good temperament. The muscat is grazed with cattle, and breeding is random throughout the year.

10.3.4 Donkey Breeds and Types of Southern Africa

Prominent breeds in the Southern African region include Tswana, Abyssinian and Namibian donkey. A recent study reported donkeys with different coat colours, including dark brown, light brown, white, grey and charcoal in South Africa's Limpopo province (Maswana et al. 2022).

10.3.4.1 Tswana

Distribution and Population Statistics: Synonym: The Tswana is also known as Botswana ass. Tswana is native to Botswana, and it is widely distributed in the country. It is also found in neighbouring regions. The population of Tswana was reported as 351,000 heads in 2015 (DAD-IS 2024). The animal is therefore not at risk.

Physical Characteristics: Tswana is a medium-sized breed with an average adult weight of 250 kg. Tswana has distinct features

Fig. 10.18 Muscat donkey in Tanzania. (Source: Wikipedia-photo by Nevit Dilmen (talk), CC BY-SA 3.0, https://commons.wikimedia.org/w/index.php?curid=11320901)

such as a short-rounded head, large, floppy and erect ears, muscularly built with well-defined withers, has varied coat colours—grey, black, brown and white (less frequent), and the belly, muzzle, nostril and eye points are white in colour (Fig. 10.19). Its main use is for draught power, transportation (Fig. 10.20), racing, riding for sports and riding by children. Tswana is also consumed, and its use as a food source is increasing in recent years.

Adaptive and Resilience Features: Tswana is well adapted to the arid and semi-arid regions of Botswana. Its resilient features make it particularly useful for draught power when compared to cattle or horse, such as (1) ability to survive drought better due to their small size and ability to survive on low-quantity/quality feed materials and lower water requirements; (2) cheaper to purchase and maintain; (3) better body condition for ploughing; (4) easier to train, handle and manage; (6) higher survival rate in areas infested with tsetse flies (cause trypanosomiasis) and African horse sickness; (7) little or no gender restriction on their use; (8) have longer working life if well managed; and (9) can be an avenue for poverty alleviation in rural areas (Nsoso et al. 2008; Nengomasha et al. 1999).

10.3.4.2 Namibian

Distribution and Population Statistics: Synonyms: okasino, donki, tonki, ndongi and donkie. The Namibian donkeys are believed to have been brought to Namibia from 1656 by White colonial settlers who used the animal as pack and draught power for on-farm activities and for pulling carts and wagons, and later spread to the rest of the country from the early nineteenth century (Mwenya and Keib 1997). The Namibian donkey population has remained steady over the years, with an estimated 120,500 heads in the northern communal areas in 1997 and about 120,000 heads in 2014 (DAD-IS 2024; Mwenya and Keib 1997).

Physical Characteristics: The breed is medium-sized, and the coat colour is varied, including greyish-brown, brown, etc. The donkey is used for transportation, draught power, meat, riding (work), transport and riding by children. Donkey meat is a delicacy in some localities in Namibia.

Fig. 10.19 Tswana adult donkey showing typical features. (Photo by Dr. E. M. Ibeagha-Awemu)

Fig. 10.20 Greyish-brown Tswana donkey ready to transport water at a collection point near Opuwo in Namibia. (© The Donkey Sanctuary 2024)

Adaptive and Resilience Features: The breed is locally adapted to the arid regions of Namibia.

10.4 Donkey Breeding and Production Systems in Africa

Donkey husbandry varies based on its purpose, herd size, usage, and environment. Efficient use of donkeys depends on many factors, including socio-economic and cultural factors. In extensive systems (Fig. 10.21), donkeys graze freely throughout the day, similar to feral donkeys in the wild. In pastoral systems, donkeys are herded with other livestock like cattle, goat and sheep. They can survive on poor diets without showing clinical signs of anaemia or metabolic disorders and are resistant to various infectious pathogens and pests common in the tropics. Unlike horses, donkeys are less prone to colic and azoturia, likely due to physiological adaptations. In *mixed and small-scale systems*, donkeys are often an additional livestock for smallholder rural dwell-

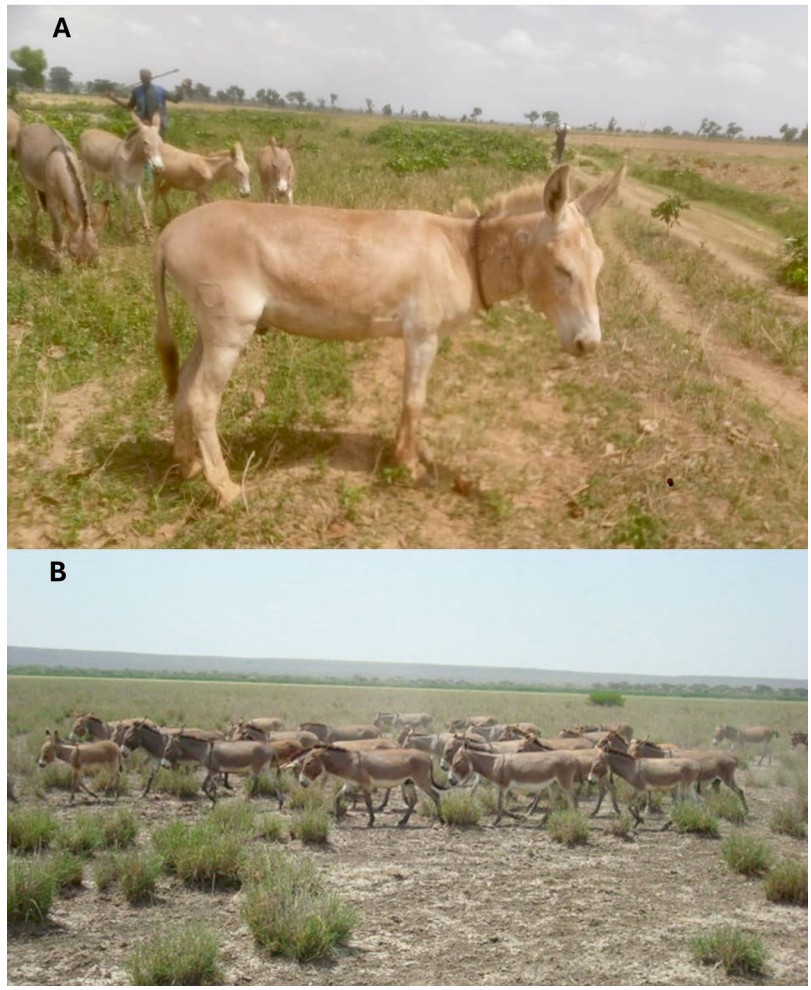

Fig. 10.21 Donkeys grazing in Zaria, Nigeria (**a**) (Photo by Dr. E. M. Ibeagha-Awemu) and in Ethiopia (**b**) (Photo by Dr. E. Kefena)

ers, primarily used for draught and transport purposes in free-range systems, which are widespread in sub-Saharan Africa. In *semi-intensive systems*, donkeys graze periodically and receive some supplemental feeding. They spend part of the day in the field and the night in a stable, fence, or barn, as seen in farms integrating donkeys with other livestock, such as dairy production in Kenya, using paddocks and fences for pasture management. See Chap. 2 for a detailed discussion on African livestock production systems.

Donkey management in Africa involves inbreeding and introgression from divergent lineages, although the inbreeding detected in African donkey populations is limited, being attributed to free-range local management practices that allow for continued interbreeding with wild and feral subpopulations (Todd et al. 2022). Admixture modelling suggests ongoing introgression from African wild asses into modern donkeys from Africa and the Southern Arabian Peninsula. Donkeys are bred throughout the world and often play an important role in agricultural activities, particularly in poorer regions and the least accessible. Traditionally, jacks are considered challenging to breed in domestic conditions, whether for natural breeding or semen collection using either jennies or mares. Donkey's natural sexual behaviour significantly differs from that of other domestic animals. This presents challenges for in-hand donkey breeding, particularly on mule studs where normally only jacks and mares are kept for breeding. In Africa, as elsewhere, donkey breeding is mostly random,

Fig. 10.22 Mule breeding in Ethiopia. Female horse (left) and male donkey (right) ready to mate. (Photo by Dr. E. Kefena, Agricultural Transformation Institute, Ethiopia)

and very little care is taken in the selection of mating pairs. Since importing of exotic breeds is practically not feasible, the risk of breed outcrossing is negligible. Limited data on donkey reproduction indicate relatively long gestation periods of about 11.5–12.5 months or 353–371 days and varying conception rates. Donkeys grow slowly, taking up to 24 months to reach maturity.

While there is limited intentional breeding of the donkey in Africa, mule breeding has been practised in many parts of the world, including Africa (Fig. 10.22), for centuries. The mule is a hybrid cross of a male donkey (jack) with a female horse (mare). The mule crossbreed of the donkey with 62 chromosomes and the horse with 64 chromosomes has 63 chromosomes, and it is infertile. The mule has been deliberately bred by man since ancient times, such as in Mesopotamia and Anatolia in the third century BC, and it was known in Egypt before 3000 BC (Babb 2017; Yilmaz and Wilson 2013). During the Roman Empire, the mule was the most frequently used beast of burden (Devriese 2012). It is believed that the mule combines valuable characteristics from the donkey and horse, making it a good work animal. The mule has the calm, stoic nature of its donkey father and a more energetic, flighty reaction of its horse mother. Unlike the horse, the mule is less likely to panic in dangerous situations and is able to carry more weight than donkeys. The role of the mule as a beast of burden is founded on these great attributes, which make it a great means of transport in remote mountain and desert environments, where roads and other transport infrastructures have failed to penetrate (Debarbieux et al. 2014; Giampiccoli 2017). These attributes prompted Guénon (Guénon 1999) to refer to the mule as the ship of the mountains, while the camel is the ship of the desert. Today, the mountain tourism industry employs mules across the world, from the Alps to the Andes and the Himalayas to the High Atlas (Giampiccoli 2017; Cousquer and Allison 2012; Blakeway and Cousquer 2018; Watson et al. 2023; Cousquer et al. 2023).

10.5 Donkey Diversity in Africa

In Africa, few studies were carried out in the field of conservation using molecular tools on donkeys. In addition, most of the studies were carried out within the framework of foreign collaborations with research laboratories or service providers. As a result, most characterisation studies

on African donkey populations focused on morphometry.

10.5.1 Morpho-Biometric Studies and Population Characterisation

During the last decade, a sparse number of phenotypical studies have been conducted to characterise the donkey populations of some regions of Africa. Morphological measurements are combined in indices to characterise the anatomic parts or whole body, coat colour variations, head and body shape, as discussed under Sect. 10.3 (donkey breeds and types). Often, this type of data is statistically analysed using multivariable descriptive analysis such as discriminatory, factorial, and clustering. Morphometric differences are then used to estimate genetic relationships between populations (Ayad et al. 2019; Kefena et al. 2011; Khaleel et al. 2020; Apagu 2016; Labbaci et al. 2018). There are no specific guidelines regarding donkey measurements, and many studies have adapted those used in horse or even other livestock species, and commonly, these studies use the methods previously reported as a reference. The major objective of this type of study is usually to establish a breed studbook (Folch and Jordana 1997) to guide breeding and conservation (Navas et al. 2017). In some studies, live weight estimations and the body condition are also used to characterise the donkey populations, e.g. (Labbaci et al. 2018) using as reference Pearson and Ouassat (2000), which also provide a very useful tool about animal welfare.

10.5.2 Genetic Diversity and Population Structure of African Donkeys

Short tandem repeats (STRs) or microsatellites have been the most popular genetic markers used for studies of genetic diversity and breeding management (e.g. paternity testing) in the donkey and other livestock species. Nonetheless, only a couple of studies were made on African donkey populations using these markers (Rosenbom et al. 2015). Examining the genetic diversity and population genetic structure of Ethiopian donkey populations with 12 equine microsatellite markers, Kefena and colleagues (2021) reported higher diversity within populations than between populations and a grouping of the populations into highland (Abyssinian, Afar and Hararghe) and lowland (Ogaden, Omo and Sinnar) genetic lineages, which agrees well with the traditional donkey classification system in Ethiopia. Using mitochondrial DNA (mtDNA) sequence polymorphism, past population demographic and spatial expansion was evident in the Ethiopian donkey populations, with Sinnar being considerably diverged from the other donkey breeds or populations (Kefena et al. 2014). Meanwhile, an Ethiopian donkey haplogroup formed the centre of a median-joining network of donkey breeds from Ethiopia, China and worldwide, which suggests Ethiopia as a possible centre of diversities for domestic donkeys in the Horn of Africa (Kefena et al. 2014).

Globally, low genetic differentiations in domestic donkeys (Rossel et al. 2008; Beja-Pereira et al. 2004; Kimura et al. 2011; Marshall 2007) are attributed to two factors: (1) no large mammals have been added to the stock of successful domesticates since the initial domestication event, implying not enough time to build up or acquire novel genetic variation within donkey populations, and (2) the fact that donkeys being initially tamed for transport probably facilitated the exchange of breeding individuals among populations across large geographic areas, which led to higher inter-population gene flow than intra-population gene flow (Marshall 2007).

With regards to the use of microsatellites markers for parentage assessment, the International Society for Animal Genetics (ISAG) recommended a set of 13-dinucleotide microsatellites loci isolated from the horse genome (AHT4, ASB23, HMS02, HMS03, HMS06, HMS07, HMS18, HTG7, HTG10, TKY297, TKY312, TKY337 and TKY343 (International Society for Animal Genetics 2017)), while the

FAO recommended 30-dinucleotide microsatellites also isolated from the horse genome, divided into six multiplex groups (AHT04, AHT05, ASB02, ASB17, ASB23, COR007, COR018, COR022, COR058, COR069, COR071, COR082, HMS02, HMS03, HMS06, HMS07, HMS20, HMS45, HTG06, HTG07, HTG10, LEX33, LEX34, LEX54, LEX63, LEX68, LEX73, NVHEQ054, SGCV28, VHL209). These represent all the autosomal chromosomes (with the exception of chromosome 6) for the genetic characterisation of donkey populations (FAO 2011). Both panels share markers and have been used in an extensive number of population genetic studies on donkey populations, e.g. (Rosenbom et al. 2015; Colli et al. 2013; Ivankovic et al. 2002; Jordana et al. 2017; Stanisic et al. 2017; Yatkin et al. 2020; Zeng et al. 2019). It is important to note that cross-species use of microsatellites has the potential to cause ascertainment bias due to the impact of the mutational process on the length of alleles, e.g. see (Li and Kimmel 2013; Dang et al. 2020). As the donkey genome is now available with good quality (Renaud et al. 2018), there is a need to map donkey-specific microsatellites.

A report on mtDNA data from ancient archaeological and historic museum samples of existing donkeys (*Equus asinus*) in Northeast Africa revealed two distinct mtDNA haplogroups, namely the Nubian wild ass (*Equus africanus africanus*) and Somali wild ass (*Equus africanus somaliensis*), with no geographical substructuring (Kimura et al. 2011). It is more obvious from a recent comprehensive study on the genome panel of 207 modern and 31 ancient donkeys and 15 wild equids by Todd et al. (2022). that current sub-populations from Kenya and the Horn of Africa best represent the descendants of the earliest donkeys. A phylogenetic reconstruction grouped modern donkeys according to sampling locations into Clade A for African donkeys and Clade B for mostly non-African donkeys (Todd et al. 2022). Further structure within Clade A separated donkeys from the Horn of Africa (Ethiopia and Somalia), plus Kenya from those from West Africa (Ghana, Mauritania, Nigeria and Senegal). Clade B also included donkeys from Nubia (Egypt and Sudan). The whole Y-chromosome sequencing of the donkey was recently reported, and the first analysis has shown low variability and discordant paternal and maternal histories (Wang et al. 2020). Nonetheless, the study lacked a fair representation of donkeys from Africa.

10.6 Conservation of the Donkey Genetic Resources in Africa

The subject of conservation of donkey genetic resources in Africa has received very limited attention in the face of growing concerns bordering on critically endangered Somali Wild Ass (AU-IBAR 2019), which is facing the risk of extinction. Other populations at risk include the Idabari of Chad and Sahel, as well as the Somali donkey. Most donkey breeds or types do not have information on population statistics that could be used to assess risk status.

In the past, donkeys in developing countries were most valued as working animals. However, their roles and economic values have changed greatly over the years. The socio-economic values of donkeys have not been fully harnessed, and the demand for donkey hides in China has triggered a global trade of donkeys. Sub-Saharan Africa exports about 1.8 million donkey hides to China annually (www.donkeysforafrica.org). Such an unprecedented rise in donkey trade is affecting the less protected and the world's poorest communities, which are still heavily dependent on donkeys as work animals (Köhle 2018).

Although the African nations urgently need to design and implement conservation plans for the donkey populations (see Chapter 25 for detailed discussion on conservation techniques), it is not feasible to conserve populations with limited information on characterisation. Therefore, more characterisation of local populations is urgently needed; otherwise, any conservation programme will be shortsighted and inefficient.

10.7 Uses of Donkey in Africa

10.7.1 Sociocultural Role of Donkey

In recent years some studies have revisited the importance of the donkey in African societies at several levels; one proposed the evaluation of its role: as a generator of income, the owner's social status, reducing vulnerability and encouraging resilience, husbandry, and gender dynamics (divisions of labour between men and women typically manifest in the allocation of different responsibilities based on societal norms and expectations), and differences between rural and urban societies (Geiger et al. 2020). This and other studies on the benefits and production challenges of working donkeys in smallholder farming systems (Gichure et al. 2020b) show a growing interest in evaluating the role of this species across Africa. For example, the variations in views and practices between urban and rural settings suggest that assessing the socio-economic value of donkeys in different locations within the same area or country is critical, rather than assuming that similar views are held between compatriots.

It must be recognised that the donkeys are increasingly at risk from external threats like environmental changes, diseases and health issues. The recent rapid emergence of the donkey skin trade to meet global demand for the raw materials to make the traditional Chinese medicine (*ejiao*) is a risk factor to African donkey populations. The trade has resulted in escalating donkey theft in many African countries and has wide consequences for donkey welfare and the livelihoods of some of those who depend upon them. Future studies on the implications of this global trade for the socio-economic value of working donkeys within their communities are needed.

10.7.2 The Role of the Donkey in Household Management and Income Generation

The donkey plays a significant role in supporting household chores and in generating income (Fig. 10.23). In rural areas, donkeys are often used in farming and for transportation; they pull ploughs and carts, deliver goods to market, and collect water from wells (Fig. 10.24). In urban areas, they are mainly used in construction, transport of people and goods, and garbage collection (Angara et al. 2011a; Maggs et al. 2021; Smith

Fig. 10.23 Donkeys at a livestock market in Niger. (Source: Wikipedia.com- photo by Vincent van Zeijst, CC BY-SA 4.0, https://commons.wikimedia.org/w/index.php?curid=82422085)

Fig. 10.24 Women fetching water to be transported by donkeys at a collection point near Opuwo in Namibia. (©The Donkey Sanctuary 2024)

2004; Valette 2014). In Ethiopia, 56% of households keep donkey for pack services (for income generation and household use), 26% for cart service (income generation), 14% for pack use by household and 4% exclusively to rent for breeding or petty trade to generate income (Admassu and Shiferaw 2011). In the Hulet Eju Enese district of Ethiopia in particular, the donkey is mainly used for pack (100%) and cart (34%) services and mule for riding (83%), pack (57%) and cart (34%) services, as well as renting out to other users (Ayalew et al. 2018). In Algeria, the Casbah neighbourhoods of Algiers (capital of Algeria) are mostly inaccessible by car, so the donkey is the sole alternative means of transportation of goods and people. By participating in work, donkeys boost the economic capacity of a region so much that in Ethiopia, there is a saying: 'If you don't have a donkey, then you are a donkey'. It has been reported that the income derived from the use of equines (including donkeys) in Ethiopia accounted for 14% of total income compared to 13% from other livestock (Admassu and Shiferaw 2011).

Millions of people across the world spend several hours every day collecting safe, clean water from near and distant locations. The donkey plays a major role in transporting water for household use, farming and livestock feeding. The donkey reduces the labour and time required to perform these tasks. The extra income generated through working animals also allows people to save money, reinvest in growth, and fund access to education. Donkeys' ability to transport

Fig. 10.25 Donkey pulling cart with woman in Somali. (Source: Wikipedia and available at https://en.wikipedia.org/wiki/List_of_donkey_breeds#/media/File:AMISOM_Djiboutian_Contingent_in_Belet_Weyne_11_(8212396061).jpg, CC0 1.0 license)

goods increases the potential for wider access to quality nutrition through local food markets. The donkey is therefore a valuable asset to many owners. Besides working, donkeys increase productivity by reducing the time and labour in the field or on-farm transportation, they enable farmers to reach inaccessible markets or areas. This allows farmers to sell their crops while allowing the community to access more diverse foods.

Owning a working donkey or animal is a major source of empowerment for women who rely on it to do tasks they would otherwise have to perform themselves, from collecting water and tilling the land to transporting goods to and from the market and from the fields (Figs. 10.24 and 10.25). By enabling women to be economically active, they also increase their economic and community status. This economic capability can prevent the worst form of destitution for lone women, whether working in rural or urban settings. Since donkeys assist in vital chores, parents can give children the adequate attention they need at home.

10.7.3 Role of the Donkey in Agriculture

In small-scale farming systems, the donkey has advantages over machinery due to its low cost of maintenance and environmental safety. Traction capability differs between animals, mainly depending on their body weight. For different species, however, the proportion of power provided based on body weight can vary. For bullocks, it is 12% of body weight, for buffaloes also 12%, for camels 18%, whereas the traction capability of the donkey is 24% of its body weight, which is superior to that of bullocks (12% of body weight), buffaloes (12% of body weigh), and camels (18% of body weight). Thus, the draft ability of donkeys is therefore superior to that of other draft animals. An earlier study showed that a pair of donkeys can generate a draught force equivalent to 15–20% of their body weight with no abnormal sign of fatigue. The average weight of a pair of donkeys is about 250 kg, and they can produce adequate force to do tillage work in light soil (Orhan et al. 2012; Bekele et al. 2001). For these and other reasons, donkeys are of crucial economic importance in many developing countries. Since ancient times, donkeys have been used in Africa, Asia, and Europe to transport people and goods, as well as to pull carts and light ploughs. Although they are not as fast as horses, donkeys are more cost-effective to own and maintain. They have been employed for farm tillage (Fig. 10.26), threshing of grains, drawing of water and milling, for example (Jones 2010).

Fig. 10.26 Donkeys ploughing a field at a Fulani settlement in Zaria, Nigeria. (Photo by Dr. E.M. Ibeagha-Awemu)

Donkeys are an undervalued power source in a large part of the world. Their potential to work is very high, and their contribution to any household or even national economy is considerable (Valette 2014). Generally, the buying and selling price of donkeys is far below their true value, which should be calculated based on the work they give over the 14 years they can work, if well cared for. If a donkey works 6 h a day, 4 days a week, over many years, it will have given about 15,000 hours of work (Orhan et al. 2012; Bekele et al. 2001). The low price of donkeys, therefore, reflects the distorted perception of their role. However, growing donkey slaughter across Africa for their skin has triggered the regulation of the trade in donkey skin in some African countries, leading to a better perception of its value.

10.7.4 Role of Donkey in Transportation

The use of donkey is closely related to road infrastructure and the price of rural transport. It is very common in Khartoum to see working donkeys either pulling carts (91.1%) or utilised as pack animals (8.9%) (Angara et al. 2011b). At the city centre, transportation of building and domestic materials by the donkey is most prominent, while transportation of water and people is common in remote areas (Angara et al. 2011b). In Nigeria, the oil boom era led to massive importation of small 4-wheel drive trucks (i.e., pickup trucks), and these became the preferred means of transportation of farm produce to the market. The prices of both vehicles and fuel were so low that many farmers sold their donkeys, and donkey keepers in the semi-arid regions turned to other enterprises. However, once the recession set in at the end of the 1980s, the economics of motorised rural transport became more doubtful, and farmers became anxious to acquire donkeys again. Having receded in Nigeria, the donkey is once again spreading (Blench 1992).

An individual donkey can carry more than one-third of its body weight (i.e., between 40 and 80 kg), twice as much as the quantity that human beings can carry (Fig. 10.27), relieving women of much time and energy-consuming work (Valette 2014). Donkeys can be used to transport people, young and vulnerable animals, water, firewood, manure, and farm inputs and produce, as depicted in Fig. 10.25. Mules, too, can make excellent pack as well as ride animals. Being larger and stronger, they can carry more but are more expensive to maintain than a donkey (Pearson et al.

Fig. 10.27 Donkeys transporting humans, goods and animals at Zaria, Nigeria. (Photo by Dr. E.M. Ibeagha-Awemu)

2003). In urban and peri-urban regions of Ethiopia, youths generate income by using donkey and other working animals to transport merchandise (Metaferia et al. 2011; Saville et al. 2020). In 2016, the United Nations recognised working equids as working livestock and considered them critical to the livelihoods and resilience of millions of families in low- and middle-income countries (Saville et al. 2020).

10.7.5 The Donkey in Household Nutrition

For centuries, donkey meat and milk have been consumed in many parts of the world. While donkey meat is forbidden in some communities in Africa, it is regarded as an affordable source of protein in others. In West Africa, it is commonplace to trade donkeys for their meat when they are sick, exhausted or old. In 2017, the demand for donkey meat and hide increased following trade restrictions on donkey hides by many African countries (ScienceX 2017). In Turkana County of Northern Kenya, donkey milk, meat and blood are widely consumed as a source of protein (Twerda et al. 1997). There is a general conception that portrays donkey meat as dangerous for human consumption, resulting in its general lack of acceptance as a source of protein in many communities. Thus, the consumption of meat and milk from donkey has not been fully adopted due to a lack of knowledge and legislation regarding production and benefits (Hassan et al. 2022). For example, in Kenya, most licences offered to legalise slaughterhouses for donkeys are export-only licences, which can be attributed to the taboo around the consumption of donkey meat locally (Hassan et al. 2022; Chege 2016). Europe in recent years has seen an increase in the consumption of donkey meat and milk, including an increase in the number of donkey dairies in Italy, Serbia and Turkey (McLean and Navas Gonzalez 2018). For example, a Serbian donkey dairy farmer produced cheese (named pule) from donkey milk, which has been tagged the world's most expensive cheese, as it sold for up to £880/kg (Kriel 2017). Meat from donkey is also a desired product in Denmark, Germany, France and China. The rise in the donkey meat and milk industry is helping to increase the populations of rare breeds in Europe, especially those facing extinction (Kriel 2017).

In recent years, interest in donkey products (meat, milk and hide) has been increasing due to research data portraying the importance of these products. Donkey meat contains low fat and cholesterol contents, a favourable fatty acid profile, and is rich in iron (Polidori et al. 2008). The concentration of minerals in donkey milk is higher than in human milk, and it is considered safer and more similar to human milk than milk from other livestock, and it is recommended as an alternative to infant milk (Polidori et al. 2008; Fantuz et al. 2012). Donkey milk is considered to have properties such as antidiabetic, antioxidant, antimicro-

bial and antiproliferative properties that could contribute to the management of diseases (Hassan et al. 2022). Donkey milk is also used as a cosmetic, and it is rich in vitamins and polyunsaturated fatty acids.

10.7.6 Use of the Donkey in Festivals, Sports (Racing) and Leisure

In addition to its prominent use as a means of transportation and draught power, the donkey also plays prominent roles in festivals and entertainment, with ceremonial roles in funerals and religious services such as weddings (Geiger et al. 2020; Admassu and Shiferaw 2011; De Klerk et al. 2020). Donkey race is a major attraction at Lamu's annual Maulidi festival. At over 700 years old, Lamu, a quaint island town off the coast of Kenya, is amongst the oldest inhabited Swahili townships on the planet and is Kenya's oldest continuously occupied settlement. In its heyday, it served as one of Africa's most important international trading hubs. Donkeys have been cemented in Lamu's history from its early days and were increasingly important during the time of the trade. To preserve the traditional culture of the community and due to its narrow streets and sandy pathways, the government banned the use of all cars (even bicycles), leaving the donkey as the only form of transport within the old town. One of the few motor vehicles allowed in the old town is an ambulance for donkeys. Today, donkey racing forms a part of Lamu culture. During the celebration of its annual Maulidi festival, Lamu's inhabitants and visitors gather to watch thrilling donkey races (Figs. 10.28). Lamu's donkeys, which also serve as companions and as an essential means of transportation of persons and goods (Fig. 10.29), take centre stage in exciting competitions to win prizes for their owners. This festival is a celebration of Lamu culture and history and includes dhow (sailboat) racing, which is also important in Lamu's history. Although there are donkey racing events in several destinations or locations, the race through Lamu's old town is a sight that cannot be rivalled (Figs. 10.28).

10.7.7 Use of the Donkey in Medicine and Onotherapy

Onos is the Greek word for donkey, and onotherapy is the term for therapy with the help of donkeys. With onotherapy, the physical and behavioural characteristics of the donkey can be valued (small in size, soft to the touch, affectionate and patient, with slow movements). Because of these characteristics, the donkey can offer valuable services to people affected by a disability or discomfort, with results that can be noticed quickly and can be documented (Karatosidi et al. 2013). The activities of 'Mediation with the Donkey' propose a methodology of reappropriation of man and animal. It allows rediscovering the cultural warmth of relationships through which man acquires a greater awareness of the identity of the donkey and the sense of their shared roles in history (Karatosidi et al. 2013). Today, in the context of culture, there is a continuing attempt to reconcile man with the environment in which he lives, especially with animals. The rediscovery of the relationship between man and animal is a journey through time to rediscover the harmonious relationship they had in the past. It is a practice that uses horseback riding as a therapeutic 'tool' and it is a combination of education and rehabilitation techniques, aiming to succeed on a sensory, motor, emotional or behavioural injury of man (Borioni et al. 2012). Some activities cover a therapeutic purpose because they affect the general health of a person. The achievement of a state of psychological wellbeing also influences the general health of an individual. Positive moods significantly affect behaviour, mental processes, and the expression of emotions and good feelings in humans. In this sense, the work done during onotherapy aims to achieve a higher state of wellbeing (Borioni et al. 2012).

Donkey hide is a highly sought commodity for the manufacture of a traditional Chinese medicine known as 'ejiao'. Ejiao is therefore believed to have a variety of health benefits, such as treatment of reproductive problems and improvement of blood circulation (Kriel 2017; DS 2017).

10.8 Challenges of the Donkey Enterprise in Africa

10.8.1 Limited Information on Donkey Keeping

Donkeys have altered human history as vital beasts of burden for long-distance movement, especially across semi-arid and upland environments, but remain inadequately studied despite globally expanding and providing key support to low- to middle-income communities (Todd et al. 2022). Although widespread in the Sahelian region of Africa, they are not frequently considered like other species by governments and private agencies for research and development. Thus, there is limited research attention and documentation of breed, breed characteristics and production characteristics.

10.8.2 Feed and Water Scarcity

The main constraints facing donkey farmers are lack of good quality feed and access to clean water, especially within the arid and semi-arid environments where most donkeys are raised. In Ethiopia, donkeys in most cases are left to scavenge for food with no form of supplemental feeding provided (Gebreab et al. 2004). This is especially challenging for working donkeys, which cannot scavenge low-quality grasses to

meet their energy requirements for work. In Godey town in Ethiopia, donkeys provide cart services, transport various items weighing more than 300 kg at a time and work for about 8 hours a day and 6 days per week (Hassen et al. 2022). Adequate nutrition is essential for meeting the energy requirements for growth, work and reproduction.

10.8.3 Poor Breeding Management

Donkey breeding is generally characterised by uncontrolled breeding with no human-directed selection or assisted breeding. In this system, animals mate randomly, a practice that does not promote the improvement of desirable traits. It was observed that donkeys breed during the early rainy season, which might be due to the availability of feed resources during the rainy season.

10.8.4 Diseases and Lack of Veterinary Facilities

Although donkey appear to stay healthy on varied and often poor-quality diets and with low management inputs, they are still plagued with numerous health challenges. Nine commonly encountered diseases of donkeys in northern Nigeria have been described (Blench et al. 1992). Colics (Anomari), ulcerative lymphangitis, inflammation of the tongue, interdigital dermatitis, ear sore, fistulous withers, unknown causes of lameness and a nervous system disorder called locally as 'chinkai chinkai' are frequently reported diseases affecting donkeys in some villages and towns in northern Nigeria (Bale et al. 2003). In Ethiopia, the main health problems of donkeys include back sores, respiratory problems (coughing and nasal discharge as common symptoms), bite wounds, lameness, hoof overgrowth, foot diseases, eye problems, digestive problems and high parasite burden (Hassen et al. 2022; Feleke et al. 2015). Donkeys are also susceptible to common zoonotic diseases and transboundary animal diseases such as African horse sickness, the eastern, western and Venezuelan equine encephalomyelitis, equine infectious anaemia, Equine Herpesvirus, Equine Influenza, Equine Viral Arteritis, Japanese encephalitis, West Nile Fever and rabies.

10.8.5 Poor Animal Welfare

Animal welfare in relation to donkey production is compromised in Africa due to limiting factors such as poverty and limited knowledge on donkey production and management. Often, donkeys are not given due attention because of misplaced love for them and the general notion that they are worthless. Donkeys are appropriate and economical pack animals, especially under smallholder farming systems in regions with low levels of road construction, road networks, and rugged terrain. Moreover, donkeys are used under difficult conditions such as intense heat, difficult topography, dehydration, limited water supply, poor nutrition, wounds on different body parts, hoof problems, poor housing and management practices, working for long hours, walking long distances usually carrying heavy loads, and suffering poor handling during loading and poor harnessing devices, all of which have negative impacts on the welfare and quality of life of donkeys. Paying attention to the welfare of donkeys is critically important to ensure their health and survival, which translates to enhanced livelihoods of the people who depend on them.

10.8.6 Poor Housing

Donkeys under the pastoral and smallholder production systems are mostly allowed to roam freely with no housing provided or housed in an open area by tethering around the household (Hassen et al. 2022; Tuaruka and Agbolosu 2019).

10.8.7 Policy Issues and Poor Funding

Even though the donkey contributes significantly in providing work and transportation services and in enhancing the livelihood of low-income

Fig. 10.30 Pictures show the poor slaughter, handling and disposal of donkeys in Nigeria, Kenya and Ghana as deplorable activities associated with the donkey skin trade. (©The Donkey Sanctuary 2024)

families, there are no government policies on its use and management, and no attention is given to its promotion and protection by the majority of African countries.

10.8.8 The Donkey Skin Trade

In addition to the many roles of the donkey, donkey hide products have recently gained importance for their use in a traditional Chinese medicine called 'ejiao'. The donkey hides are processed by boiling to produce a firm gel, which is dissolved in alcohol or hot water and used in beverages and beauty products. However, increased demand for the supply of donkey hides for ejiao production in China is a threat to the donkey population worldwide (Maggs et al. 2021, 2023), as over 1.8 million donkey hides are exported to China annually (www.donkeysforafrica.org). Africa's donkey population is currently in decline due to this high demand for donkey skin by China, especially in North and Southern Africa (Table 10.1). According to the Donkey Sanctuary, about 5.9 million donkeys are slaughtered yearly for their skin, using slaughter methods that are unregulated, inhumane and unsanitary, and poor handling leading to the deaths of large numbers of donkeys on their way to slaughterhouses (DS 2024). Also, the Donkey Sanctuary indicates that the trade and shipping channels used by donkey skin traders are controlled by criminals involved in wildlife, drug and arms trafficking and other illegal activities (e.g. corruption, money laundering and passport fraud). Furthermore, the handling, slaughter and transportation of untreated skins and improper disposal of donkey carcasses (Fig. 10.30) is a potential risk for the spread of infectious diseases such as anthrax and exposure to shipping workers or abattoir workers (DS 2022).

The devastating consequences of the donkey skin trade to countries and the local populations in affected areas include: (1) stolen livelihoods of

women, children and the communities who rely on donkeys for their social and economic wellbeing; (2) horrific treatment of donkeys; (3) decline in donkey populations and corresponding threat of the extinction of the species; (4) potential for the spread of zoonotic diseases such as anthrax; (5) the rate of donkey extraction is disproportionately higher than the rate of donkey multiplication through random breeding; (6) fuel commercial interest, theft and maltreatment of donkey owners; (7) misuse of government issued licences to donkey slaughter houses. The PADCO (2022) further highlighted the following: (8) negative impact on adolescent girls, and women who are already compromised by pregnancy and small children, and have to continue the burden of performing the tasks that the disappearing donkeys do, including carrying water, firewood and farm produce, with the resulting negative impacts on their health and development; (9) negative impact of the shortage of donkeys on persons with disability and the elderly which may be on their health, mobility and independence [i.e., increased dependency level]; (10) the reduction of donkey populations has a negative impact on the few surviving donkeys since they will be overworked, with a negative impact on their welfare; (11) promotion of rising insecurity within communities through donkey theft incidences; (12) increased rates of illegal cross border smuggling of donkeys; and (13) increased rates of poverty.

Consequently, the donkey skin trade has been termed a cruel and largely unregulated international trade in donkey skin by the Donkey Sanctuary, affecting African countries and the African Union (DS 2022). In 2022, the Donkey Sanctuary referred to the Donkey Skin Trade as 'A Ticking Time Bomb' (DS 2022). To curtail the impact of the trade in donkey skin on the communities that depend on the donkey, many African countries banned the trade in donkey skin by 2017, which did not have much effect. The most effective action started with the historic Dar es Salaam declaration during a Pan African Donkey Conference in Tanzania in December 2022, to an African-wide ban on the trade in donkey skin by the African Union at its 37th Summit on February 18, 2024, in Ethiopia (PADCO 2022; AU 2024).

10.9 Conclusion and Future Perspectives

10.9.1 Understand the Donkey

Intensify research efforts to characterise and document every aspect of donkey growth, development, health, reproduction, nutrition, welfare and genetics. This will generate essential baseline data that will guide efforts tailored to improving the productivity, welfare and disease management of donkeys. There is a need to enhance community awareness of the declining populations of donkeys and the role of the communities in the conservation, utilisation, and sustainable development of the donkey. Capacity building to deliver extension services to donkey owners and organisations is vital.

10.9.2 Structured Breeding

There is a need to implement structured donkey breeding and sustainable farming systems. This will require a breeding stock of high quality, which is attainable through phenotypic and genotypic characterisation of donkeys, quality nutrition and healthcare. It is imperative to develop breeding programmes in agricultural stations or within community breeding programmes to supply farming communities with stronger and healthier breeding animals, particularly to solve the rapid decline in donkey populations caused by the trade in donkey skin.

10.9.3 Economic Impact of Donkey

Current knowledge about the socio-economic value of donkeys as working livestock and as a means of transportation, as well as the impact of the donkey skin trade, is limited, highlighting the need for comprehensive research. Moreover, coordinated research on the socio-economic con-

tributions of donkeys and other equids to livelihoods, poverty alleviation, national GDP and economic growth is vital, as it will enhance the value of the species as well as attract interest to it.

10.9.4 Donkey Conservation

To effectively conserve donkeys, it is crucial to first understand their production characteristics, nutritional requirements, disease management, growth and health attributes, amongst others. Conservation plans should be developed with local community involvement, reflecting their needs and the essential role of donkeys in their livelihoods. International cooperation is also necessary to regulate the global donkey trade, establish stricter trade regulations, and promote the breeding of the donkey to satisfy the need for ejiao production. Preserving donkey genetic resources requires urgent and multifaceted approaches, including scientific research, policy development, and community engagement. By working together, it is possible to balance the demand for donkey skins with the need to conserve this vital genetic resource.

10.9.5 Donkey Welfare and Other Issues

These can be achieved by implementing the following recommendations of PADCO (2022): (1) coordinate and guide implementation of the Animal Welfare Strategy for Africa (AWSA); (2) enhance collaboration, cooperation, coordination, partnership and promote information sharing with stakeholder and resourcing organisations; (3) support the formulation of Africa's common position on animal welfare; (4) advocate for political commitment for compliance with animal welfare decisions by the African Union Commission (AUC) and Member States; (5) ensure the inclusion of working animals (Donkeys, Horses and Camels), in animal resource policies, strategies, programmes and projects at national and regional levels; (6) advocate for the development and inclusion of working animals, including donkeys and their health care in the curricula of animal health courses and professional programmes; (7) generating data on donkey populations, productivity, health care and trade in Africa to inform policy makers; (8) institute a coordinated Pan African Conference action on the exploitation and utilisation of the donkey for the wellbeing of rural communities in the continent.

10.9.6 Legislation to Protect Africa's Donkey Populations

Develop national and continent-wide policies tailored to protect the donkey, as well as strategies and programmes for the development of donkey and other equines and the donkey trade within the animal resources sector of Africa.

In conclusion, donkey serve vital roles in the livelihoods of local communities by alleviating poverty, creating job opportunities, assisting in household chores, being a source of nutrition, serving as mobile companion for pastoralists and is a means of transportation of goods and persons through terrains where other modes of transport are not feasible. The donkey, therefore, deserves attention and protection and should be included in the livestock policy planning by governments and other relevant livestock agencies.

11 African Horse Genetic Resources and Breeding Strategies for African Input Systems

Djalel E. Gherissi, Ginette Aumassip-Kadri, Mohammed E. A. Benhamadi, Félix Meutchieye, Yassine H. Jamali, and Semir B. S. Gaouar

Abstact

This chapter presents a synthesis of current knowledge on the horse in Africa in its different facets. The first part of the chapter deals with the origin and domestication of the horse and the ways in which the ancestors of this animal were tamed in Africa (Sect. 11.1 on origins and evolution of horses in Africa). The second part presents a description of the equine sector in Africa (Sect. 11.2) while exploring local and exogenous equine resources of Africa (Sect. 11.2.1 describes major African horses' genetic groups, while Sect. 11.2.2 presents physiognomy and description of the horse populations in Africa, Sect. 11.2.3 on horse production systems in Africa, and Sect. 11.2.3 on the feral "wild" horses of Africa). The third part (Sect. 11.3) describes the main structures and organizations that manage the equine sector in Africa. The fourth section provides the traditional use (Sect. 11.4.1) and equestrian sports (Sect. 11.4.2), model competition and paces (Sect. 11.4.3), equestrian games (Sect. 11.4.4), traditional sports activities (Sect. 11.4.4), and other

In Memoriam: Ginnette Aumassip Kadri (1928–2025)
This chapter is dedicated to the memory of Ginnette Aumassip Kadri, who passed away at the age of 97, on January 7th, 2025, after contributing to the preparation of this chapter and this book. A pioneer in the study of Saharan prehistory and rock art—particularly in Algeria—she was also a passionate advocate for the preservation and recognition of the Barb horse. She was the director of the Laboratory for Research on African Prehistory at Centre National de Recherches Préhistoriques, Anthropologiques, Historiques, Alger, Algeria under the auspices of Centre National de la Recherche Scientifique (CNRS), Paris, France. She taught African prehistory at various universities. Her lifelong commitment to research, cultural heritage, and the defense of this noble breed continued until her final days.
May she rest in peace.

service perspectives such as leisure and equestrian tourism, used in army and security forces and in hippophagea (Sects. 11.4.6, 11.4.7 and 11.4.8). The fifth part presents an inventory of research on the biodiversity of the African equine population (Sect. 11.5), emphasizing the main tools used in this context, namely: morpho-biometric (Sect. 11.5.1), immunological (Sect. 11.5.2), biochemical, and molecular biology (Sect. 11.5.3) studies. Finally, the last section presents the current situation of African horse production and reproduction performance and the conservation strategies of the local equine resources (Sect. 11.6). Section 11.7 presents a summary and conclusion.

11.1 Origins and Evolution of Horses in Africa

11.1.1 Origins of the Horse in Africa

The species *caballus*, the horse, did not take its current form until the Pleistocene, a million years ago. It is the culmination of many descendants dating back to the Eocene (55 to 34 million years ago) and which, four to five million years ago, gave rise to the genus *Equus* in North America. Two to three million years later, the horse was reported to have crossed Beringia and reached Eurasia, then Africa, where its presence was, for some two million years, in the form of a zebra, *Equus stenonis*.

The basic form was unearthed in 1825 in the gypsum of Paris by Cuvier and named *Paleotherium*; discovered in 1841 in London, it was called *Hyracotherium;* and then in 1876, it was called America *Eohippus*. About the size of a dog, it had 44 teeth, three fingers on the forelimbs, and four on the hind legs, all ending in pads. All the stages of its development could be followed in North America, where a long, continuous transformation has made it a prototype of evolution. It disappeared around 10,000 BC while it remained elsewhere. Over time, the multiplicity of discoveries has only led to a bushel of species, without altering the pattern.

11.1.2 The African Niche

For a long time, it was a widely held belief that no wild horse inhabited the African continent, although the genus *Equus* was seen throughout the Quaternary period in various forms; some in the ancestry of zebras and others as donkeys. The *caballus* form was not found in Africa until 1983,

when it was simultaneously discovered in the suburbs of Algiers (Bagtache and Hadjouis 1983) and the region of Tiaret (Chaid-Saoudi 1984–1986). A widely accepted hypothesis was that of Le Couteulx de Canteleu (1880), that a domesticated horse was introduced into Egypt by the Hyksos around 1500 BC, and then the Dongola diffused to the south, and the Barb to the west. The discovery of Tassili paintings in the 1950s did not support this proposition, as they depicted a square model with a convex profile, a low-set tail, a model quite distinct from the Egyptian representations of the same era, which featured an elongated body, concave profile, and slender limbs. Linguistics further reinforces this observation by revealing different roots for the word "horse" in Egyptian and North African languages (Galand-Pernet 2006).

The identification of an African wild horse through fundamental modification of the data has led many hippatrists to consider it as the ancestor of the Barb horse and possibly even the Dongola breed; the absence of wild horses was indeed the sole and insurmountable obstacle to the concept of a localized Barb horse domestication.

11.1.3 Domesticating Horses

Numerous studies concerning the species *Equus caballus* have given rise to multiple hypotheses about the domestication site of the horse. However, pinpointing the exact location of domestication remains a challenge. Based on archaeological and more recent genetic data, there is speculation that horse domestication occurred in Eurasia. The archaeological evidence is sourced from three key aspects: skeletal modifications, geographical distribution, and the human-horse relationship. Genetic data, on the other hand, stem from observations of decreasing genetic diversity and increasing variability in coat forms, particularly more pronounced since the third millennium (Epstein 1971; Arne et al. 2009). Linguistic studies, such as Lehmann (1992), associate domestication with the eighth millennium, bringing the notion of a taming period preceding domestication closer to the eighth millennium (Lehmann 1992). Well-established indications of unique connections between humans and horses from the Pontic steppe date back to around 4500 BC (Anthony 2007), these dates are quite late in the history of animal domestication.

In contemporary times, the horse population is declining in all countries due to modernization and mechanization, which have greatly diminished its roles as a warhorse, means of transportation, and racing animal. Its current distribution across the African continent is uneven and hindered by diseases like trypanosomiasis (or nagana). Most equines today are concentrated in the northern and northeastern parts of Africa, where breeds like Barb and Dongola have been documented since the second millennium BC. The introduction of horses to the southern region is recent and closely tied to European presence there (Anthony 1996).

11.1.4 Domestication Hotbeds

Two predominant questions about the horse have been posed: Is *Equus caballus*a distinct species or a subspecies known as *Equus ferus caballus*? Additionally, where and when did horse domestication occur? While no consensus exists regarding the answer to the first question, the second question has generated diverse hypotheses that have replaced earlier propositions (San 1869; Franck 1875). If horse domestication happened in the cradle of civilization in Central Asia, then only one location is established, leading to a single ancestral origin for the horse that subsequently dispersed (Edwards 1973).

Consequently, horse domestication is attributed to the SrednyStog culture, dating back to 4000 BC, primarily due to a notably high concentration of horse bones, predominantly young males, and the discovery of objects that could be interpreted as horse bits in Dereivka, Ukraine (Anthony 1996). More ancient leg relics of domesticated horses are found in Khvalynsk, Russia, where horse remains accompany those of domestic cattle, sheep, and goats in graves dating from 4800 to 4400 BC (Anthony 2007). Other

potential centers, such as the Pontic Steppes, Anatolia (Benecke 2006; Arbuckle 2012), Hungary-Romania, Portugal, and Spain (Digard 2002) were initially suggested, but subsequently discarded.

A particular point of interest emerges from the Botai culture that flourished around 3500 BC in Kazakhstan, particularly Krasni Yar and its environs (Outram et al. 2009). These sites contained corrals with horse dung, and pottery preserved traces of mare's milk. Recent research reveals that the Botai horse is not the ancestor of today's domesticated horse; rather, it gives rise to the Przewalski horse, a breed that was tamed rather than a true wild horse (Gaunitz et al. 2018).

An African cradle?

Traditionally, it has been widely accepted that the introduction of the horse into Africa in a domesticated state occurred during the eighteenth or fifteenth century BC, coinciding with the Hyksos invasion of Egypt. Subsequently, the horse spread southward, giving rise to breeds like the Dongola and the Barb, which in turn contributed to the ancestry of most other African horse breeds. However, a challenge to this narrative arose in the 1950s with the discovery of cave paintings depicting horses that differed from those associated with the Hyksos. Gautier (1952) and other researchers examining this discrepancy in North Africa concluded that the absence of wild horses not only hindered, but definitively ruled out, the notion of a local origin (Gautier 1952). This obstacle raised questions about the unique bond between the Maghreb people and their horses.

In 1983, the identification of a wild horse species, *Equus algericus*, at two sites—one near Algiers (Bagtache and Hadjouis 1983) and the other close to Tiaret (Chaid-Saoudi 1984–1986)—along with its presence at various sites spanning from 40,000 to 8000 years ago (Bouzid 1991; Hadjouis 1993), revived the issue and brought forgotten discoveries back to the forefront (Thomas 1879; Reygasse 1922). The consideration of a local origin addresses the quandary posed by artistic representations and human behavior. This perspective aligns with the findings of Lira et al. (2010), who suggest the possibility of an independent domestication occurring in the Iberian Peninsula or North Africa because of specific haplotypes found on the peninsula (Lira et al. 2010). This view is also supported by paleontologist Chaid-Saoudi (2006), who noted a shared "geographical and paleontological area between Southern Europe and the Maghreb" (Chaid-Saoudi 1984–1986).

Jansen et al. (2002) observed a striking similarity in phenotype between Barb and Iberian horses (Jansen et al. 2002). Variants of Barb horses, identified by Ouragh (2006), are exclusively shared with populations having historical connections, distinguishing them from other breeds (Ouragh 2006). Oelke (undated) isolated a D1 genotype (Iberian / Barb), which diverged from the A6 mother genotype around 500,000 BC. These converging lines of evidence point toward a local domestication of the Barb horse, completely independent of other horse breeds.

11.1.5 The Reasons for Domestication

It is widely accepted that domestication arises from material needs, but its development necessitates a favorable cultural and social context. In the case of horse domestication, it signifies a novel requirement that aligns with a process closely associated with the impacts of climate change. Numerous rationales have been put forward for this phenomenon. Chiefly, it revolves around the notion of a "food reserve," encompassing both meat and milk. Archaeological evidence from the Botai culture highlights that horses constituted a significant portion of their meat consumption. However, during the presumed period of domestication, the steppe's grasses reached towering heights of up to two meters, making the hunting of numerous horses impractical. It is postulated that humans would have captured some of these horses to utilize them as mounts for protecting their herds. Thus, aside from providing sustenance, horses would have become invaluable hunting companions.

Religious considerations also emerge as a motivating factor, manifested through horse burials and the practice of hippophagia. These practices may be intricately tied to shamanic rituals aimed at assimilating the virtues of the horse. Digard (2004) highlights the allure of "fiery, fast, and powerful" game, alongside the innate human desire for ownership and possession (Digard 2004).

In Africa, the earliest evidence of domesticated horses comes from pastoral regions that underwent desertification. As herds required significantly larger territories to thrive, the question arises as to whether horse domestication was instrumental in safeguarding these herds. The prospect of domestication within this same region is not implausible. In the TassiliAjjers region, an even older, painting dating possibility to the eighth millennium depicts an arrangement of diminutive equines with small ears. However, representations from this era have primarily focused on humans, with only four animal species, including the giraffe, antelope, and mouflon, bearing indications of domestication or attempts at domestication. The quest remains ongoing to identify a site analogous to Dereivka or Krasni Yar that could definitively address this question.

11.1.6 Number of Horses in Africa

As of 2021, according to FAO data, there were 60,193,503 horses worldwide, distributed across the five continents (FAO DAD-IS 2021). In Africa, there were 7,412,943 (FAO DAD-IS 2021) with an annual increase rate of about 2% (see Chap. 1: African livestock production systems: The past, present and the projected future). The African continent accounts for 21.31% of the total global horse population, resulting in a lower ratio of 5.3 horses per 1000 people compared to the global ratio of 7.7 horses per 1000 people. South America boasts the highest horse population, while Oceania has the lowest.

Horse populations in African countries vary widely, influenced by factors such as economy, culture, and their diverse uses. Ethiopia has one of the continent's largest horse populations, primarily used for transportation and agricultural labor. Chad and Mali also heavily rely on horses for farming and transportation needs. Senegal houses a significant number of horses utilized for various purposes, including agricultural work. Nigeria has a growing equine sector with a substantial horse population.

In North African countries, there is a higher concentration of horses due to longstanding equestrian traditions. Egypt and Sudan have a rich history of using horses, particularly in agriculture and transportation. In South Africa, a well-established equestrian industry supports a significant horse population, used for various purposes, including sports and leisure. On the other hand, some regions may have smaller horse populations, and these horses remain integral to their respective countries, playing significant roles in various aspects of daily life.

11.2 Equine Sector in Africa

11.2.1 The Major Horse Genetic Groups of Africa

At present, the African equine population is primarily characterized by two predominant groups: the Barb and the Dongola breeds. The north coastal area is characterized by the Arabian horse type. The western variation of it is called the Barb, and it is distinguished also by blood polymorphisms (Ouragh 2006). Most African breeds are derived from this Barb type and from Dongola varieties adapted to the north-east and central African environments. The Dongola practically disappeared in its homeland, and residual populations can be found only in Sudan and in the western lowland of Eritrea. Emerging during the second millennium, these two populations have served as the foundation for numerous breeds or lineages.

The Chap. 1 of this book states that the total number hose breeds is 134, distributed respectively as follows: 10 breeds in the Eastern Africa, 5 breeds in Central Africa, 20 breeds in Northern Africa, 61 breeds in Southern Africa and 38

breeds in Western Africa, The United Nations Development Program (UNDP) has identified a total of 98 distinct breeds resulting from the geographic isolation of specific groups of horses. This adaptability is a key trait of horses, as they possess remarkable plasticity in their morphology, enabling them to readily conform to their environment. However, this adaptability encounters a subtle hindrance in the form of the tsetse fly, which poses a significant challenge. Covering over a third of the continent's land area, the presence of the tsetse fly and its effects are influenced by fluctuating climate conditions (Devisse 1995).

11.2.1.1 Barb Horse

Origin and Breed Distribution

The Barb horse is notably distributed across North Africa (Algeria, Libya, Morocco, Tunisia), where it originated through the domestication of the wild form, *Equus caballus algericus* (Fig. 11.1).

The Barb horse likely serves as the ancestor of several small horse breeds across different regions. In the southeast of Mauritania, particularly in Tagant, it is referred to as the *Hodh* or the horse of Hodh. In Mali, it is known by various names such as *Banamba, Bélédougou*, and possibly *Barouéli* or *Gueniekalari*, and even referred to as the horse of *Nioro* (Ndiaye 1978). Additionally, similar small horse breeds include the *Bobo* in Burkina Faso and the *Bhirum* or *Pagan* in Nigeria. In Senegal, the *M'Bayar,* which was introduced through trans-Saharan trade during the Middle Ages, potentially has roots dating back to the eighth-seventh centuries BC. The *M'Par* or *Cayorrose*, situated between the Senegal and Saloum rivers, represents three small horse varieties closely resembling each other (Dupuy 1995). The *Koto-koli*, a pony related to the *Barb*, is the smallest breed in West Africa and can be found in Burkina Faso, Nigeria, and Togo. In northern Benin, the *Berba* is a specific type of *Koto-koli* named after the ethnic group that breeds it. Some specialists suggest that the *Mogods* or *Nefza* pony in Tunisia exhibits Barb influence, a notion that is partially supported by research on blood protein polymorphism (Chabchoub et al. 2006).

The Barb horse serves as the progenitor of various breeds or sub-breeds, with one of the most prominent being the Arab-Barb (Jamali 2020). This lineage emerged in Algeria at the end of the nineteenth century through the crossbreeding of local Barb broodmares with Arab stallions imported from the Near East. Arab-Barbs were raised in Algeria as well as in Morocco, Tunisia, and Chad (Husser 2017; Jamali 2020). In their region of origin, an open studbook recognizes any horse with Arab lineage ranging from 25% to 75% as Arab-Barb, resulting in a diverse array of models.

Physical Characteristics

The Barb horse from Algeria exhibits specific physical characteristics that highlight its unique attributes. This breed stands at an average height of 152.2 cm at the withers and 150.1 cm at the rump, with a total length of 160 cm and a scapular-iliac length of 118.2 cm. Notably, the Barb horse showcases dimensions such as an ilium length of 37.4 cm, thigh width of 45.8 cm, and shoulder width of 54.4 cm. Circumference measurements include 175.5 cm at the chest, 40.4 cm at the forearm, 30.1 cm at the knee, 28.6 cm at the ball, 19.8 cm at the anterior cannon, and 20.6 cm at the posterior cannon (Benhamadi et al. 2017). These physical attributes are further indicated with various indices such as the body profile index of 0.95, signifying its well-proportioned build, and the compactness index of 2.68, reflecting its overall compactness. The body mass index is 1.51, while the Dactylorthracic index is 0.11. These indices indicate the breed's distinctive features. Finally, the relative body index is 0.91, showcasing its relative harmony (Benhamadi et al. 2017). The Barb horse breed possesses an average body weight of 409.9 kg (Benhamadi et al. 2017). This comprehensive physical description underscores the uniqueness and individuality of the Barb horse breed, making it appreciated within the equestrian world. Reported results confirm that the Barb horses from Tiaret and Laghouat regions in Algeria adhere to the international

Fig. 11.1 Barb horses. (**a**) Barb horse from the national stud farm "Chaou-Chaoua" in Tiaret, Algeria (Chikhaoui et al. 2018) (Image credit: (Chikhaoui et al. 2018)); (**b**) Moroccan Barb horse used for Fantasia (Talley 2015) (Image credit: Gwyneth Ursula Jean Talley); (**c**) Barbe horse breed in Mauritania (Photo Courtesy: Ministry of Rural Development, Mauritania) (AU-IBAR 2019), (**d**) Mounted Barb horse in Nigeria (Image credit: Eveline M. Ibeagha-Awemu)

standard for the Barb horse breed (Benhamadi et al. 2017).

Although the Barb horse possesses attributes such as a prominent forehead, broad chest, and sturdy limbs associated with fast-moving saddle horses, it does not excel in speed races when compared to the Thoroughbred. This is primarily due to its elongated features, including a long shoulder, back, kidney, and relatively shorter forelock. However, the Barb horse holds its own in endurance races, especially over long distances, given its morphological similarities to the Thoroughbred Arab. In fact, it can be a significant competitor to the latter in endurance raids, with some enthusiasts even considering the Arab-Barb hybrid as the best choice for this challenging discipline (Benhamadi et al. 2017).

Moreover, the Barb horse's wide limbs and robust joints contribute to its "safe foot," rating, making it an excellent candidate for novices of horseback riding. It is also noted for treks in rugged and remote mountainous terrains. The Barb horse's adaptability to various equestrian disciplines underscores its versatility and value within the world of equine sports and recreational riding (Benhamadi et al. 2017; Jamali 2020).

Husbandry Practices

Barb horse husbandry is a harmonious blend of cultural reverence, adaptability, climate management, endurance focus, and conservation commitment. These practices ensure that the Barb horse remains a symbol of North African culture and a breed celebrated for its exceptional traits and adaptability across various roles. The husbandry practices for the Barb horse in North Africa are distinctively characterized by the keepers' unwavering commitment to heritage preservation and the cultural significance of the horse. Breeders and owners take immense pride in maintaining the breed's genetic purity, thus ensuring that the Barb horse's unique traits, such as agility, endurance, and a docile temperament, are passed down through generations. This dedication is practical and deeply rooted in the cultural fabric of the region, making Barb horse care a symbol of tradition and cultural heritage.

What sets Barb horse husbandry apart is the breed's exceptional versatility and adaptability. These horses excel in diverse roles, from equestrian sports (conventional and nonconventional sport as indicated in the section "Use of the Horse in Africa" below) to agricultural work and livestock herding. Consideration of North Africa's unique arid environment demand specialized care practices susch as the provision of shelter from extreme weather conditions. However, the hallmark of Barb horse husbandry is the unwavering focus on its endurance. These horses are renowned for their stamina, and their care and training are geared toward enhancing their endurance capabilities, especially in long-distance riding and racing. Furthermore, active participation in conservation efforts marks the Barb horse husbandry practices as a proactive and preservation-oriented.

Production Systems

The husbandry practices for Barb horses in North Africa combine traditional wisdom with modern care standards. These practices not only ensure the health and performance of these remarkable horses but also safeguard their cultural relevance and significance in the region. The production systems for Barb horses in North Africa encompass a wide range of activities and goals, reflecting the breed's adaptability and historical significance in the region. One prevalent production system is rooted in tradition, where Barb horses are employed in herding livestock and assisting with agricultural tasks. These horses play essential roles in rural communities, embodying cultural heritage and providing indispensable support in day-to-day activities.Another prominent production system revolves around equestrian sports and racing, particularly endurance riding. Breeders and owners focus on conditioning and training Barb horses to excel in competitive events. This production system emphasizes physical fitness and stamina development, allowing these horses to showcase their remarkable endurance capabilities. In regions with picturesque landscapes and challenging terrains, Barb horses are employed in tourism and recreational riding. These systems aim to pro-

duce reliable and sure-footed horses that can navigate rugged environments, offering tourists and adventurers memorable experiences.

For those dedicated to preserving the purity and unique traits of the Barb horse, breeding and conservation programs take center stage. Selective breeding ensures that the breed's distinct characteristics, such as agility and docile temperament, are perpetuated. These programs often include genetic testing and pedigree recording to maintain the breed's integrity. Some production systems involve crossbreeding Barb horses with other breeds to enhance specific attributes or create new breeds tailored to particular purposes. Improvement programs may focus on refining performance capabilities or adapting the Barb horse to different climates and roles. Traditional training methods, passed down through generations, are still relevant in some production systems. These methods emphasize the development of a horse's innate abilities and temperament, aligning with the breed's historical roles and showcasing its versatility. The diverse production systems for Barb horses in North Africa reflect their adaptability and rich history. From traditional practices and cultural heritage to competitive sports, conservation efforts, and tourism, these systems cater to various purposes, highlighting the breed's enduring significance and its ability to thrive in a variety of roles.

11.2.1.2 Dongola

Origin and Breed Distribution

The origin of the Dongola breed is still uncertain. It owes its name to the province of Dongola where the hyksos horse is said to have established itself, a hypothesis which needs to be reconsidered in the light of current knowledge. When John Burckhardt traveled to the Nubian region in the 1880s, he found that the Dongola horse was famous throughout Sudan, Ethiopia, and the rest of the Near East. He stated that the breed was originally from Arabia, and it was one of the finest he had seen: "the horses possess all the superior beauty of Arabian horses, but they are larger." Burckhardt also noted that a prime stallion was worth five to ten slaves and that the Mamluks were particularly interested in Dongola horses (Epstein 1971; O'Fahey 1980).

The Dongola is however very close to the Barb horse. Its presence in Eastern Africa or its wildness suggests a very old introduction (Fisher 1972) (Figs. 11.2 and 11.3). In addition to its involvement is creating of the *Arewa* varieties of horses, the Dongola developed under various names such as the *Kreikibat* in the south-east of Mauritania, the *Todori,Noungou* or *Fada*, *Hausa*in Niger, under the names of *Bobo Oulé, Boulsa, Boussougha, Boussouma, Dori* in Burkina Faso as well as *Bahr el Ghazal, Kréda,* and *Ganaston* in Chad. The *Kirdimi* is perhaps a type of Dongola or the product of a cross with the Barb.

Physical Characteristics

The Dongola has a convex profile, a rather large head, a flat chest, and long and thin legs and croup, which detracts from its attractiveness. Standing at about 152–155 cm at the withers, the Dongola does not have an imposing presence. Its back is long, and its loins are rather poorly attached. Many Dongola horses have white markings on their faces and lower legs. In addition, the typical Dongola horse has a black or chestnut-colored coat. However, the most common color is a deep, reddish bay.

H. Epstein maintains that the "original breeding center of the Dongola begins that noble race of horses justly celebrated all over the world…. What figure the Nubian breed would make in point of fleetness is very doubtful, their make being so entirely different from that of the Arabian; but of beautiful and symmetrical parts, great size and strength, the most agile, nervous, and elastic movements, great endurance of fatigue, docility of temper, and seeming attachment to man, beyond any other domestic animal, can promise anything for a stallion, the Nubian is, above all comparison, the most eligible in the world" (Heidorn 1997).

Husbandry Practices

The original Dongola horse breed is on the brink of extinction due to interbreeding with the Arab, Barb, and Arab-Barb crossbreeds. Some attribute

Fig. 11.2 Dongola horses in Eritrea (Ministry of information of Eretria 2021)

Fig. 11.3 Dongola horse (Koçkar 2012). (Reproduced with permission CC-BY 4.0 license)

the decline in their population to inadequate management practices. In Sudan, stallions are given preference over mares, leading to the mating of strong stallions with weak mares, which results in offspring of inferior quality. Today, the Dongola horse is primarily used as a riding horse, typically standing at a height of 15–15.2 hands. They are often showcased in festivals and ceremonies, adorned in traditional attire (Mason 1996; Porter et al. 2016; Hendricks 1995).

11.2.1.3 Other Breeds

In addition to the indigenous horse breeds, various foreign breeds have been introduced over time, leading to the formation of their distinct lines and sub-breeds. The Arabian breed is believed to have been introduced to Egypt in the fourth century from the Arabian Peninsula (Olsen 2017). Having gained prevalence in the Maghreb, the Arab horse was brought to Algeria in 1870 and subsequently spread to Tunisia, Morocco, and several other Western countries.

In Algeria, a unique population of Arab horses was developed exclusively in Tiaret for over a century (Fig. 11.4). This population is notable for not having a male lineage for nearly a hundred years; all stallions originated from the breed's homeland. Until 1978, the breed consisted solely of "ASSIL" horses, maintaining its original lineage (Fig. 11.5). Algeria was awarded the WAHO trophy for the first time in 2010. The trophy was awarded to the excellent stallion Diable Du Desert after he won the most prestigious race in the country, the "Grand Prix du President de la Republique." (Fig. 11.4a). After that, Sakhi stallion was awarded Algeria's WAHO trophy for the year 2014 at the age of 6 years. This was in recognition of his winning the title of Senior Champion Stallion at the Algerian "Salon Du Cheval 2014" National Arabian Horse Show (Fig. 11.4b). In 2016 WAHO trophy was awarded to the 17-year-old mare, Fousha (Fig. 11.4c), bred at the Tiaret State Stud (Algeria), a lovely mare, with excellent conformation and type, descended on her

Mare, 1999., Breeder: Haras Nationaux, Jumenterie de Tiaret with Mr. Ahmed Bouakkaz, General Director and Head of Stud Book at ONDEEC, and the owner Mr. Zeguaoui Abed, WAHO 2016 trophy winner

Fig. 11.5 Typical Selale riding horse (Kefena et al. 2012)

dam line from Orkana [Fari II (GB) / Karillon (GB)], who was imported to Algeria from Sweden in 1978. Fousha was awarded the WAHO trophy in respect of her winning success during the major "Salon du Cheval de Tiaret" show, held in September 2016.

The Thoroughbred breed is found in various regions, including South Africa, Algeria, Kenya, Lesotho, Morocco, Tunisia, and, to a lesser extent, Cameroon, Ghana, Senegal, and Sudan. In Sudan, crossbreeding Thoroughbreds with local and Arabian horses resulted in the Sudanese breed. Furthermore, crossing Thoroughbreds with Sudanese horses gave rise to the Tawleed breed.

In areas where trypanosomiasis prevails, the horse populations consist primarily of foreign breeds or those with recent foreign ancestry. This is observed in countries like South Africa, Zambia, and Kenya. In South Africa, the Basuto breed was created in the nineteenth century through a combination of Arabian, Thoroughbred, and Cape horses. It subsequently evolved in the challenging environment of Lesotho. Influenced by Barb and Indonesian horse breeds, the Basuto contributed to the development of the Nooitgedacht breed in Botswana, alongside the Tswana and Boerperd breeds. The Boerperd breed from South Africa is a revival of the historical Boer or Cape Horse, an almost extinct breed established in the seventeenth century through the blending of various imported breeds. The modern Boerperd breed emerged from two varieties: Cape Boer and South African Boer. These breeds are the result of incorporating Flemish, Hackney, and Cleveland Bay bloodlines. The Vlaamperd breed, bred in the Cape region, originated from crossings between Frisian, Thoroughbred, Hackney, and Cape horse breeds. While rare, the Vlaamperd is highly protected due to its uniqueness and limited population.

11.2.2 Physiognomy and Description of the Horse Populations in Africa

11.2.2.1 Indigenous Horse Breeds

The aboriginal horse breeds in Africa are the Dongola in Eastern Africa and the Barb in North Africa. Both breeds are believed to have spread to the Sahelian region, undergoing changes and interactions with each other and with local populations. These preexisting equine herds probably arrived during the Caballine period around nineteen centuries BC. Additionally, some Arabian

horses accompanied the latest invasions. This theoretical pattern still requires confirmation or affirmation through genetic research over a larger timescale (including fossils) and larger spatial scale, encompassing the entirety of Eastern, Northern, and Western Africa.

While transitioning from drylands to tropical zones, horses underwent certain morphological and physiological modifications that were initially considered as degeneration (Marcenac 1969; Doutressoulle 1947). It is questionable, however, whether an increase in hardiness or tolerance to trypanosomiasis is truly a degeneration. History and geographic constraints have shaped uniform equine populations. At times, humans have selected the finest individuals for hunting, racing, warfare, and raids. The culmination of this multifactorial process resulted in the creation of superbly gifted horse breeds, such as the Dongola, Barb, Arabe-barb, or a combination of these breeds.

It is worth noting that the borders of African countries do not always align with the ranges of these breeds. For example, the Dongola and the Barb are cross-border breeds. The numbers of local indigenous horses in each country are presented in Table 11.1:

Table 11.1 Horse population by African countries (FAO DAD-IS 2021)

Order	Area	Value (heads)
1.	Ethiopia	2,192,443
2.	Chad	1,379,167
3.	Sudan	794,045
4.	Mali	607,786
5.	Senegal	582,927
6.	Sierra Leone	445,118
7.	South Africa	328,220
8.	Niger	260,861
9.	Morocco	190,000
10.	Nigeria	107,357
11.	Egypt	84,387

36.	Mauritius	150
37.	Congo	68
38.	Democratic Republic of the Congo	–
39.	South Sudan	–

Selale or Oromo

Origin and breed distribution: The Selale, also known as Oromo, is an indigenous horse breed of Ethiopia commonly found in the highlands of the central plateau, in the northern region of Shewa. The most typical form of this breed originates from the Wichale and Jida districts. There is no official census of their population.

Characteristics: Selale horses are well-conformed saddle horses bred by the Oromo ethnic group. They are said to be influenced by some English stallions imported by Emperor Haile Silassie in the 1930s and 1940s. Morphologically similar to the Abyssinian horse (Kefena et al. 2012). The reference measurements recorded in the DAD-IS databases are an average of 1.296 m for females and 1.337 m for males (Kefena et al. 2012). The Selale horses are taller and have a more elongated body and limbs compared to other Ethiopian horses (Fig. 11.5). These horses have a symmetrical conformation and are perceived as elegant, representing the typical saddle horses of Ethiopia. Their topline is straight, and their legs are slender. The stallions have a well-developed crest,

which symbolizes the Ethiopian saddle horse (Kefena et al. 2012).

Uses: Indigenous horses in Ethiopia are extensively used for transport, traction, and agricultural work such as ploughing.

Kafa

Origin and breed distribution: Tropical forest of Sheka and Keffa zones, from the rainforests of Sheka and Keffa in the southern nations.

Description and Morphology: The Kafa is a well-conformed and robust breed. The average recorded height in the DAD-IS database is approximately 1.26 m for mares and 1.33 m for males. The Kafa is among the largest horse breeds (Fig. 11.6) in Ethiopia and exhibits the characteristics of a "heavy forest horse" type. In terms of morphology, the Kafa closely resembles the Horro and the Bale but is notably different from the Selale. It has a higher wither height, a longer body length, and a larger chest circumference compared to other Ethiopian horses. The chest and shoulders are deep, and the body is robust with well-rounded ribs. The mane is often long and typically falls on the right side of the neck. There is no studbook or population estimate for this breed (DAD-IS 2010). These horses typically live outdoors throughout the year and rarely have access to shelters. A subsequent genetic study in 2017 classified the Kafa in the same genetic group as the Selale.

Uses: The Kafa horse is the largest among the Ethiopian horse breeds and is primarily employed for draft purposes in hard areas.

Abyssinian

Origin and breed distribution: The Abyssinian is a horse breed originating from northern Ethiopia. The breed is also known as "Galla," but this name is considered offensive by the Oromos (Mason 1996; Porter et al. 2016). It is often confused with the Oromo horse. The Abyssinian horses are believed to have arrived in Ethiopia through the Red Sea coast. They were exported to England in the 1860s (Rousseau 2014). The Abyssinian horses are distributed in the North and north central parts of Ethiopia, particularly in the Semien Mountains in the area of Gondar, in the Amhara region (Kefena et al. 2012).

Description and morphology: The DAD-IS database reports an average height of 1.25 m for females and 1.29 m for males (DAD-IS 2010) (Fig. 11.7). The height can vary significantly. The Abyssinian is closely related to the Arab-Barb but has irregular morphology, often characterized by a bulging belly and frequently a hollow back

Fig. 11.6 Kafa stallion (Kefena et al. 2012)

Fig. 11.7 Director of Parks Mather insists on A. W.'s being properly mounted on an Abyssinian horse. (Harris 1952)

(Rousseau 2014). Their chest circumference is often smaller compared to other Ethiopian horse breeds, and their overall size is generally more compact (DAD-IS 2010). This is attributed to the intensive use of the breed for work (Kefena et al. 2012). These horses come in various coat colors. A distinctive feature is their dense coat and a mane that grows in a disheveled manner. Many of them have green eyes due to the presence of a specific gene (Mason 1996; Porter et al. 2016; DAD-IS 2010). In terms of characterization, the Abyssinian differs morphologically from the Bale but is very similar to the Selale. These two latter breeds belong to the same group (Kefena et al. 2012). There is no official studbook for this breed.

Uses: The Abyssinian horse is used for a wide range of tasks, particularly for pulling and transportation, including plowing and hauling loads. They serve as the primary source of animal traction in their native region. Despite their small size, Abyssinian horses are valued for their strength and ability to live and work in mountainous areas (Fig. 11.8) (Kefena et al. 2012; DAD-IS 2010).

Bale

Origin and breed distribution: The Bale horse is a horse breed native to the eastern part of Ethiopia. The characterization of this breed is relatively recent, dating back to 2012 (Kefena et al. 2012). Little known, Ethiopian horses were often collectively referred to as "Abyssinians" in written sources without distinction. A characterization study focusing on 45 stallions and 55 mares of a distinct breed specific to the Bale region was published in 2012 (Kefena et al. 2012). There is no studbook for this breed (DAD-IS 2010).

Description and morphology: The morphology of this breed is considered less advantageous, characterized by a hollow back and a bulging belly.

The reference measurements recorded in the DAD-IS database show an average height of 1.255 m for females and 1.292 m for males (DAD-IS 2010). These horses are described as typical Ethiopian ponies. Their conformation is considered "flawed," characterized by a bulging belly, a short and hollow back, and a coarse body (Kefena et al. 2012). They have

Fig. 11.8 Pair of Abyssinian horses engaged in cropland cultivation. (Kefena et al. 2012)

Fig. 11.9 Bay Bale horse. (Image credit: Laika ac from UK 2014). Reproduced with permission—CC-BY 4.0 license

deep chests and shoulders, long necks, and tails compared to other Ethiopian horse breeds (Fig. 11.9). In comparison to other Ethiopian horse breeds, the Bale has deeper chests and shoulders, a longer neck, and a shorter back (Kefena et al. 2012). Among the other Ethiopian horse breeds, the Bale is closely related to the Horro but is very different from the Abyssinian and the Selale. It falls into the same group as the Horro and the Kafa (Kefena et al. 2012).

Uses: These horses are used for draft work and transportation, especially for pack carrying (DAD-IS 2010).

Borana

Origin and breed distribution: They are raised by Borana Oromo pastoralists, particularly in the area of the city of Megga in southern Ethiopia. The Borana-Oromo who breed them are organized in the *Gadaa* system and consider horses as equal if not superior to humans (Coppock 1994). There is no known census of the population (Helland 1980; Mulualem et al. 2015). The breed was recently described by Epstein in 1971, who referred to it as an "African pony (Kefena et al. 2012). They are exclusively saddle horses with a significant cultural importance and are subject to rituals.

Description and morphology: There is no studbook for this breed. It remains to be fully characterized. Its coat is always bay, and it exhibits great resistance to drought. The general conformation of the Borana breed is typical of lowland Ethiopian horses (Fig. 11.10). There is no specific size characterization due to the difficulty in measuring these animals (Kefena et al. 2012; DAD-IS 2010). The coat of the Borana horse is uniformly bay.

Uses: The breed is particularly hardy and resilient to the recurring droughts that affect its region. The Borana horse is primarily used for mounted transportation, but according to oral tradition in its breeding area, it is not permitted to be harnessed (DAD-IS 2010).

These horses hold significant cultural value through the *Gadaa* system, a code of conduct toward animals, which mandates, for example, that horses have priority access to water sources before any person or other animal. Additionally, during the dry season, these horses are regularly led to water points. Male horses receive a burial ceremony similar to those organized for humans upon their death.

Wilwal

Origin and breed distribution: It is concentrated in the east of Ethiopia at the Djidjga region (the traditional Ogaden). The origin of the breed is unknown, particularly due to the absence of written sources (Kefena et al. 2012; Coppock 1994). These horses are locally known by the names Wilwal, Ogaden, Dirdaa'u, or "Somali" horses. According to oral tradition, these horses are believed to have arrived in Ethiopia from the neighboring Somalia, originating from the Nugaal Valley (Kefena et al. 2012). The name "Wilwal" is said to come from the surname of Governor Wilwal Farah Hersi, who was well-

Fig. 11.10 Borana horse riding. (Sirikoi 2023)

known in the region for using horses of this breed in fighting against British colonists (Kefena et al. 2012). However, this theory is not confirmed by demographic and historical studies, which have yet to be conducted (Kefena et al. 2012). There is no stud book for this breed (Coppock 1994). Nowadays, this horse breed can be found in the cities of Jijiga, Dhik, Kebribeya, and Waju. Some of these horses of this breed live in the wild in Aware, near the border with Somalia. There is no inventory of the population in the DAD-IS database (Kefena et al. 2012; Coppock 1994).

Description and morphology: It is a draft horse with a regular conformation (Kefena et al. 2012), rather large and elegant (Coppock 1994). The breed could not be characterized by Kefena et al. (2012) in terms of size because the animals refused to stay still (Kefena et al. 2012).

Uses: It is a beautiful, well-conformed horse, used as saddle horses and cart horses (Kefena et al. 2012).

Horro

Origin and breed distribution: It is a breed of small draft horses originating from the western part of the central plateau of Ethiopia. These horses are found in the Horro district, located in the Oromia region. The breed is considered to be widespread (Kefena et al. 2012), but the DAD-IS database does not provide any population figures. There is no studbook for this breed, and it is not mentioned in the 2016 edition of the CAB International encyclopedia (Mason 1996; Porter et al. 2016; DAD-IS 2010).

Description and morphology: The Horro breed was recently characterized through the doctoral thesis and study by Effa Delesa (Kefena et al. 2012), which included a total of 95 horses from this population identified within eight Ethiopian domestic horse breeds. Most of these horses are considered ponies: the average recorded height in the DAD-IS database is 1.25 m on average for mares and 1.28 m for males (Kefena et al. 2012). In terms of morphology, the Bale and Kafa breeds are very similar to the Horro; these three breeds also belong to the same group, which also includes the Abyssinian, Ogaden, and Selale (Kefena et al. 2012). The morphology is irregular, with these horses being characterized by a defective physical appearance (Fig. 11.11) (Kefena et al. 2012). The chest circumference is similar to that of the Selale and Bale breeds. The genetic diversity of this breed is good.

Uses: It is used for traction, transportation, and plowing, which makes it an extremely useful horse despite its unsound conformation. It is especially used for carrying heavy loads (Kefena et al. 2012).

Kundido

Origin and breed distribution: This population of horses gets its name from the Mont Kundudo, where they have been living in the wild for a long time (Helland 1980; Mulualem et al. 2015). Very little historical information is available because there are no written sources (Kefena et al. 2012; Paris 2014). According to oral tradition collected from the oldest local residents, these horses have been known for over 200 years. It is said that Emperor Haile Selassie I captured one of these horses with the help of his uncle at the age of ten (Kefena et al. 2012; Viganò 2014). One oral hypothesis about the origin of these horses suggests that their ancestors could be military mounts that remained in the area after the war between Adal and Ethiopia in the sixteenth century. It is possible that a small group of 10–15 horses survived despite the past presence of lions and leopards, but there is no tangible evidence to support this theory (Viganò 2014).

The relatively close genetic distance between the wild horses of Kundudo and domestic horses of the Abyssinian breed suggests that the Kundudo horses may be a subpopulation of Abyssinian horses that returned to the wild in the recent past, possibly during the military events of the sixteenth century (Kefena et al. 2012).

The horses of Mount Kundudo were rediscovered in the early twenty-first century during an exploration of specific ecozones for Ethiopian horses. In 2008, researchers found a single mare of about 11 years in the region, showing no signs of domestication. They collected her DNA and nicknamed her "Basra (Viganò 2014)." In total, 18 horses were recorded in the area in October

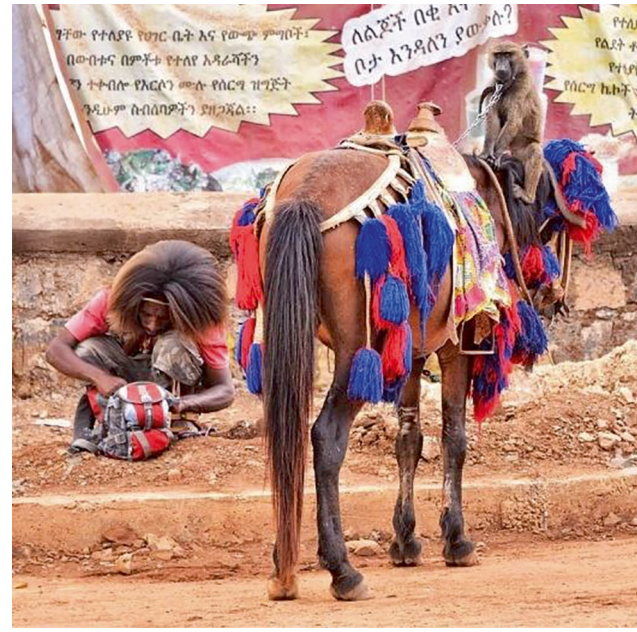

Fig. 11.11 Horro horse in Street Jimma, Ethiopia. (Image credit: Rod Waddington 2014)

2010, but in 2013, an expedition by the Ethiopian Biodiversity Institute could only count 11 horses (Kefena et al. 2012; Viganò 2014).

There is no studbook for this breed. Some of these horses are undergoing a process of redomestication, as they are captured annually by a local farmer for use in work (Mason 1996; Porter et al. 2016; Kefena et al. 2012; DAD-IS 2010).

The DAD-IS database does not provide any figures, but it is important to note that the population of these horses is extremely small. They are primarily located in the region of Mount Kundudo in eastern Ethiopia, where they are considered rare (Kefena et al. 2012; DAD-IS 2010). These horses graze on an area of 13 hectares and drink from a water source located at the summit of the mountain, which never dries up even during the hot season. They represent the last wild horses in East Africa (Viganò 2014). Their survival is seriously threatened due to their rarity, inbreeding, poor breeding practices, and demand for their foals (Kefena et al. 2012; DAD-IS 2010). Since 2011, this animal population has been classified as critically endangered (Paris 2014). The Ethiopian Biodiversity Institute has implemented conservation measures, including collecting and freezing semen from stallions (Paris 2014). The significance of this breed in the context of its connection to Ethiopian history has been emphasized (Kefena et al. 2012).

In 2016, CAB International cited the breed as "virtually extinct," as the last count in 2013 recorded only 11 horses, a number far too small to ensure the long-term survival of this population (Mason 1996; Porter et al. 2016).

Description and morphology: The morphology of the Kundudo horses is described as defective (Figs. 11.12 and 11.13), including irregular shapes, a short back with a sloping topline, and a potbelly (Kefena et al. 2012; DAD-IS 2010). However, the small number of horses studied does not allow for consistent morphological data to be deduced.

The Kundudo horses are one of the eight horse breeds identified in Ethiopia. Among these, the Borana breed, which is the most genetically distant from the Kundudo, shows the greatest genetic divergence (Kefena et al. 2012). The Kundudo is assigned its own gene cluster. The closest Ethiopian breed to the Kundudo is the Abyssinian (Kefena et al. 2012). The population also exhibits low genetic diversity, the lowest among all the studied Ethiopian horse populations. It is likely that these horses have experienced genetic drift due to a small number of founding individuals, isolation over an extended period, and no cross-

Fig. 11.12 Kundudo mare with foal. (Paris 2014)

Fig. 11.13 A thin white Kundudo mare standing on a rocky mountain slope with few trees. (Paris 2014)

breeding with horses of external origin. However, their genetic heritage is not exceptional or unique compared to other similar equine populations (Kefena et al. 2012).

Uses: Even though these horses have returned to a wild state and constitute one of the three "feral" horse populations in Africa, some of them are regularly captured by a local farmer who puts them to work during the harvest season before releasing them (Viganò 2014). They are reputed to be of limited utility for this purpose, with low pulling power, and they tend to resist the work required. However, this farmer has likely captured or sold some foals (Viganò 2014).

Studies recommend gradually transforming the grazing area at the summit of Mount Kundudo into a tourist attraction, following the model of the Namib Desert horses, capitalizing on the tourist potential of observing wild horses (Kefena et al. 2012). The Namib Desert horses are indeed globally known, albeit erroneously, as the only "wild" horses in Africa (Kefena et al. 2012).

Gharkaoui

Origin and breed distribution: The breed is native to the regions of Kordofan and South Darfur in Sudan. The breed is known by many names (listed in the DAD-IS database), including "Sudanese Western Pony," "Darfur Pony," Kordofani, Mayray, Reziegi Taaishi, and Messeri (DAD-IS 2010). It was formed in the early twen-

tieth century and likely descended from the Barb horse, with crossbreeding with Arabian and Thoroughbred horses occurring during the twentieth century, especially in the 1950s and 1960s, under the influence of the Sudanese government at the time (Rousseau 2014). It is widely distributed in southern Darfur and southwestern Kordofanalso in southern Chad (Rousseau 2014).

The only population survey published, dating back to 1994, reported a population of 8000 to 10,000 individuals, with a declining trend. A study conducted by Uppsala University, published in August 2010 for the FAO, indicated that the Western Sudan Pony is an African local horse breed that is not threatened with extinction. There is no more recent information available about this breed.

Description and morphology: Gharkaoui is the smaller of the two commonly found horse types in Darfur (O'Fahey 1980) (Fig. 11.14). According to the Delachaux guide, it stands at 1.40–1.45 m (Rousseau 2014). DAD-IS reports an average height of 1.40 m, with a weight of 400 to 450 kg (DAD-IS 2010). CAB International distinguishes the Gharbui, which has an average height of 1.47 m, from the Darfur Pony (Mason 1996; Porter et al. 2016).

As a riding horse, it resembles the Barb horse, with a convex profile head, short and muscular neck, and long, slender limbs (Rousseau 2014).

It usually has a bay, chestnut, or gray coat with white markings (Rousseau 2014). According to CAB International, the Gharbui typically carries primitive markings (stripes) (Mason 1996; Porter et al. 2016). Mares typically nurse their foals until they are 7 or 8 months old (Rousseau 2014).

Uses: It is locally ridden, including in equestrian sports, and used for light traction (Rousseau 2014).

Tawleed

Origin and breed distribution: The creation of the Tawleed breed is a result of Sudan's colonial history before its independence, with the influence of Britain and Egypt. During the British era, equine breeding was significantly influenced by imports of English horses. The Tawleed breed originated from crosses made with the local Sudan Country-Bred (SCB) horse, along with various breeds of foreign origin, especially the English Thoroughbred (DAD-IS 2010; Rousseau 2014). The initial goal was to produce a riding horse (Mason 1996; Porter et al. 2016).

The importation of English and European horses to Sudan increased in the mid-twentieth

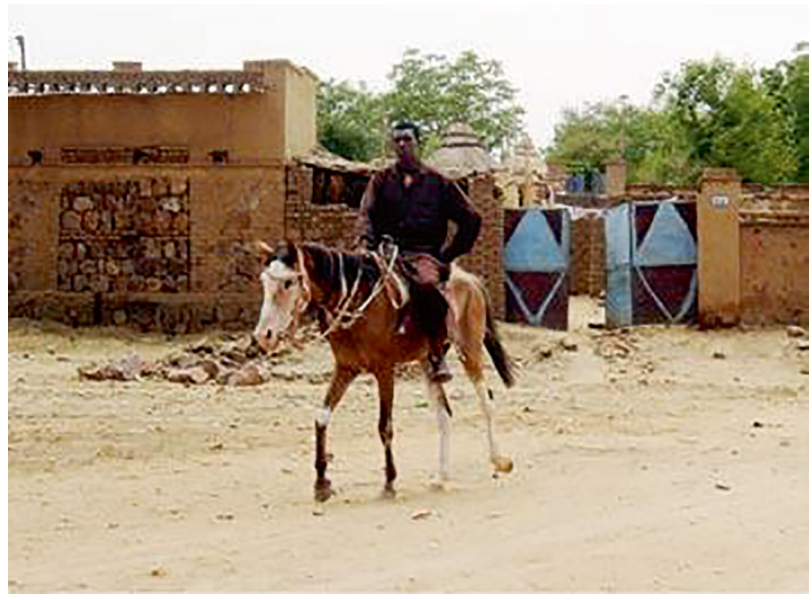

Fig. 11.14 Gharkawi horse. (Image credit: Sean Woo 2004)

century, initially to facilitate polo for colonists. After Sudan gained independence in 1956, these horses were left behind and acquired by local people. Tawleed horses gained a great reputation in Sudan, but many crosses were made with other local breeds.

The Tawleed is considered a local breed specific to Sudan, raised only in the Khartoum region (DAD-IS 2010; Meyer 2019). The study conducted by Uppsala University, published in August 2010 for the FAO, lists the Tawleed as an African local horse breed with an unknown level of threat (Khadka 2010). The threat level for this breed in Sudan is also not provided in the DAD-IS database (DAD-IS 2010), which does not contain any population data. It is likely a rare breed, with perhaps around a hundred individuals (Porter 2020).

Description and morphology: The Tawleed is a light and harmonious-looking blood horse compared to other local African breeds (Fig. 11.15). It has a straight head profile. The breed lacks resistance to the climatic conditions of its breeding region, including drought, food shortages, and the absence of shade (DAD-IS 2010; Rousseau 2014; Porter 2020). The coat can be black, bay, chestnut, or gray (DAD-IS 2010). There is no selective breeding, breed association, or studbook management for Tawleed (DAD-IS 2010).

Fig. 11.15 Tawleed horse. (Image Credit—Omdurman-Tuti Island jetty, Sudan)

Uses: It is primarily used for equestrian sports, particularly racing in the Khartoum region. The influence of the Thoroughbred has given it significant racing speed (Rousseau 2014).

The Bahr el-Ghazal

Origin and breed distribution: The breed is also known as "Kréda" (Cadéac et al. 1914) or "Ganaston" (Mason 1996; Porter et al. 2016; DAD-IS 2010). It is generally considered a particularly pure type or lineage of the West African Dongola, specific to the Bahr el Ghazal region in Chad. Most sources describe it as a variety of the West African Dongola (Mason 1996; Porter et al. 2016; DAD-IS 2010; Hendricks 2007). The breed enjoyed a strong reputation during the first half of the twentieth century in Chad and neighboring countries.

Horses do not adapt well to humid regions due to the presence of tsetse flies. As a result, breeding is more common in sub-desert regions such as Kanem, Bahr el Ghazal, and Khozzam.

The study conducted by Uppsala University, published in August 2010 for the FAO, lists the Bahr el-Ghazal as an African local horse breed that is not threatened with extinction. The threat level for the breed is not provided in the DAD-IS database, which records a population of fewer than 10,000 individuals in 1994.

Description and morphology: Measurements provided in the DAD-IS database indicate an average height of 1.50 m and a weight of 350–450 kg. A 2004 FAO study indicates a weight range of 350–400 kg (DAD-IS 2010). These horses are known for their light conformation, being elegantly and gracefully built (Batello et al. 2004).

Their coat is typically dark, often bay or black, with extensive white markings on the legs, a broad blaze on the head, and white under the belly (Mason 1996; Porter et al. 2016). They often have heterochromia, where their eyes have different colors. The breed is resilient and energetic.

Uses: It is a hot-blooded horse, particularly renowned for racing and for hunting.

Logone Pony (Kirdipony)

Origin and breed distribution: The DAD-IS database reports a multitude of French names for these animals: *Poney Kirdi*, *Logone*, *Mbai*, *Pagan*, *Poney Hoho, Poney de la Kabia, Sara*, and *Lakka*. Other confirmed names include Cameroonian Pony, Mousseye Pony, and M'baye (Mason 1996; Porter et al. 2016; DAD-IS 2010; Gouraud 2002).

The origins of the Logone pony are not well-documented (Rousseau 2014), but it is found in Cameroon and Chad, in West Africa (Mason 1996; Porter et al. 2016; DAD-IS 2010). The breed may have descended from the Barb horse and could be related to the Nigerian breed, with natural selection allowing it to adapt to its harsh environment. It was used for war and hunting, and its geographic isolation preserved it from crossbreeding with other horse breeds (Rousseau 2014). There are many descriptions of these small horses owned by the Marba-Musey people living in the floodplains along the Logone River, in southwestern Chad and northern Cameroon (DAD-IS 2010).

In 1987, 7500 Logone ponies were recorded in Chad, with a declining trend (DAD-IS 2010).

These ponies mainly inhabit the vicinity of the Logone River. The Logone pony is registered as a local African breed in southwestern Chad, along both banks of the Logone River (DAD-IS 2010). It is also found in northern Cameroon (Mason 1996; Porter et al. 2016). As of 2007, it is not considered endangered according to the FAO (Khadka 2010). However, in Cameroon, the breed is considered a relic of the past and is endangered (as of 2003) (FAO 2016 2003). Efforts by Cameroonian authorities aim to preserve it. Its resistance to tsetse flies may enable its breeding in other African regions.

Description and morphology: The average size recorded for Chadian ponies in the DAD-IS database is 1.24 m for females and 1.26 m for males, with an average weight of 175 kg (DAD-IS 2010). CAB International's dictionary indicates a median height of 1.22 m (Mason 1996; Porter et al. 2016). The Delachaux guide provides an average height of 1.25 m at the withers (Rousseau 2014). These ponies exhibit Barb-type characteristics (Mason 1996; Porter et al. 2016), being small and sturdy, with a moderately concave profile, lightly pronounced brow ridges, and small ears (Rousseau 2014) (Fig. 11.16). They have a short, thick neck and a long back. Their legs are short but strong, with small hooves. They have a shaggy mane and a tail set low (Rousseau 2014).

The most common coat colors, according to CABI, are bay and gray (Mason 1996; Porter et al. 2016), while the Delachaux guide indicates bay as the most frequent, followed by chestnut, with some roan and dun coats (Rousseau 2014). This breed is likely resistant to African trypanosomiasis and is known for its extreme hardiness and robustness, allowing it to carry heavy loads (Mason 1996; Porter et al. 2016; DAD-IS 2010). They are reputed to have gentle temperaments and light gaits (Rousseau 2014).

Uses: These ponies primarily serve as mounts or for various agricultural tasks, and could potentially make good mounts for children (Rousseau 2014). They are used both for riding and as draft animals, and are highly respected by the Musey people. It is central to many rituals resembling

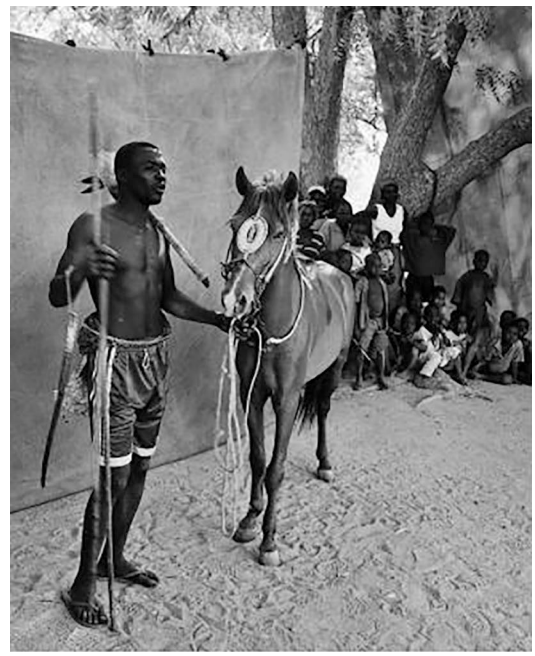

Fig. 11.16 Poneys musey à Gobo (Arthus-Bertrand 2003). (Image credit: Seignobos C). (Arthus-Bertrand 2003)

rites of passage. It has been used as a form of currency and is almost treated as an equal of a human being. Owners of these ponies generally take great care of them. Upon their death, it is not uncommon for owners to bury and mourn them (Mason 1996; Porter et al. 2016; Rousseau 2014). Traditional healing practices were used for these ponies without resorting to surgery, although this practice has declined. The consumption of horse meat is unthinkable for the Musey people (Rousseau 2014). They have developed natural resistance to trypanosomiasis, a disease transmitted by tsetse flies that infest the Logone River (Fig. 11.17).

The Seno-Gondo or Bandiagara

The Bandiagara horse, originating from Mali and Niger in Africa, is a medium-sized horse breed known for its docile nature. This breed, characterized by its Barb-type lineage and delicate yet charming facial features, has shown remarkable adaptability to the challenging climatic conditions of its region. With an average height ranging from 142.24 to nearly 152.4 cm, these horses possess distinctive physical attributes, including short and thick necks, ample chests and shoulders, long backs with rounded croups, low-set tails, robust yet sinewy legs, and hard, small hooves, making it able to fight in rocky terrains (Dehoux et al. 1996). Traditional coat colors for the Bandiagara horse include grey and bay. In terms of temperament, they are recognized for their spirited and bold nature, making them well-suited for purposes such as transportation and cart hauling (http://www.theequinest.com/breeds/).

The Banamba or Beledougou

Origin and breed distribution: The Bélédougou horse, also known as the Banamba horse (DAD-IS 2010; Doutressoulle 1952), is a horse breed originating from Mali and belonging to the group of West African Barb horses. It is traditionally raised in a prosperous region by the Marka people (Doutressoulle 1952). In her essay on the Bambaras in 1954, Pâques (1954) described the Bélédougou horse as "a Barb transformed by climate and man," with the breeding center located in the Touba canton, 90 km northeast of Koulikoro (Pâques 1954). Bélédougou is a local African horse breed with an unknown level of threat (Khadka 2010). The level of threat to the breed is also not provided in the DAD-IS database, which does not offer any population data (DAD-IS 2010).

Description and morphology: The Bélédougou horses exhibit the typical characteristics of West African Barb horses (Mason 1996; Porter et al. 2016). The southern Bélédougou horse was described as generally small (1.34–1.44 m) to well-built, narrow, and unattractive (Challamel 1904; Pierre 1905). The Bélédougou are medium-sized horses, approximately 1.45 m to 1.50 m (Doutressoulle 1952). They are known to be more muscular than horses from desert regions (Dechambre 1921).

Uses: They are used for riding, light draft work, and pulling (TheHorseGuide.com 2010) (Fig. 11.18).

The Nara Horse or Hodh Horse

Origin and breed distribution: The Mechdouf tribe, who raise these horses, trade some of them as far as the banks of the Senegal River, where they influence the local breed, the River Horse. The Mechdoufs are the most famous horse breeders among the Moorish tribes at the beginning of the colonization of Africa (Ndiaye 1978). They regularly descend to the banks of the Senegal River to sell their surplus horses, usually foals. They keep their stallions and broodmares for reproduction (Ndiaye 1978).

This horse breed is also known as the "Barb of Hodh." The Hodh horse is presumed to be descended from the Barb breed (Mauny 1965), which was widely distributed throughout West Africa and the Sahel (Elfasi and Hrbek 1988). According to the tradition of Mechdouf breeders, their so-called "purebred" horses are descended from the four mares taken as loot from the Arabs, with the first one being scabby (Doutressoulle 1947). During the colonization of French West Africa, the Hodh horse was described as one of the best horse models in all of French West Africa (Doutressoulle 1952).

The DAD-IS database and the CAB International encyclopedia classify it as a regional

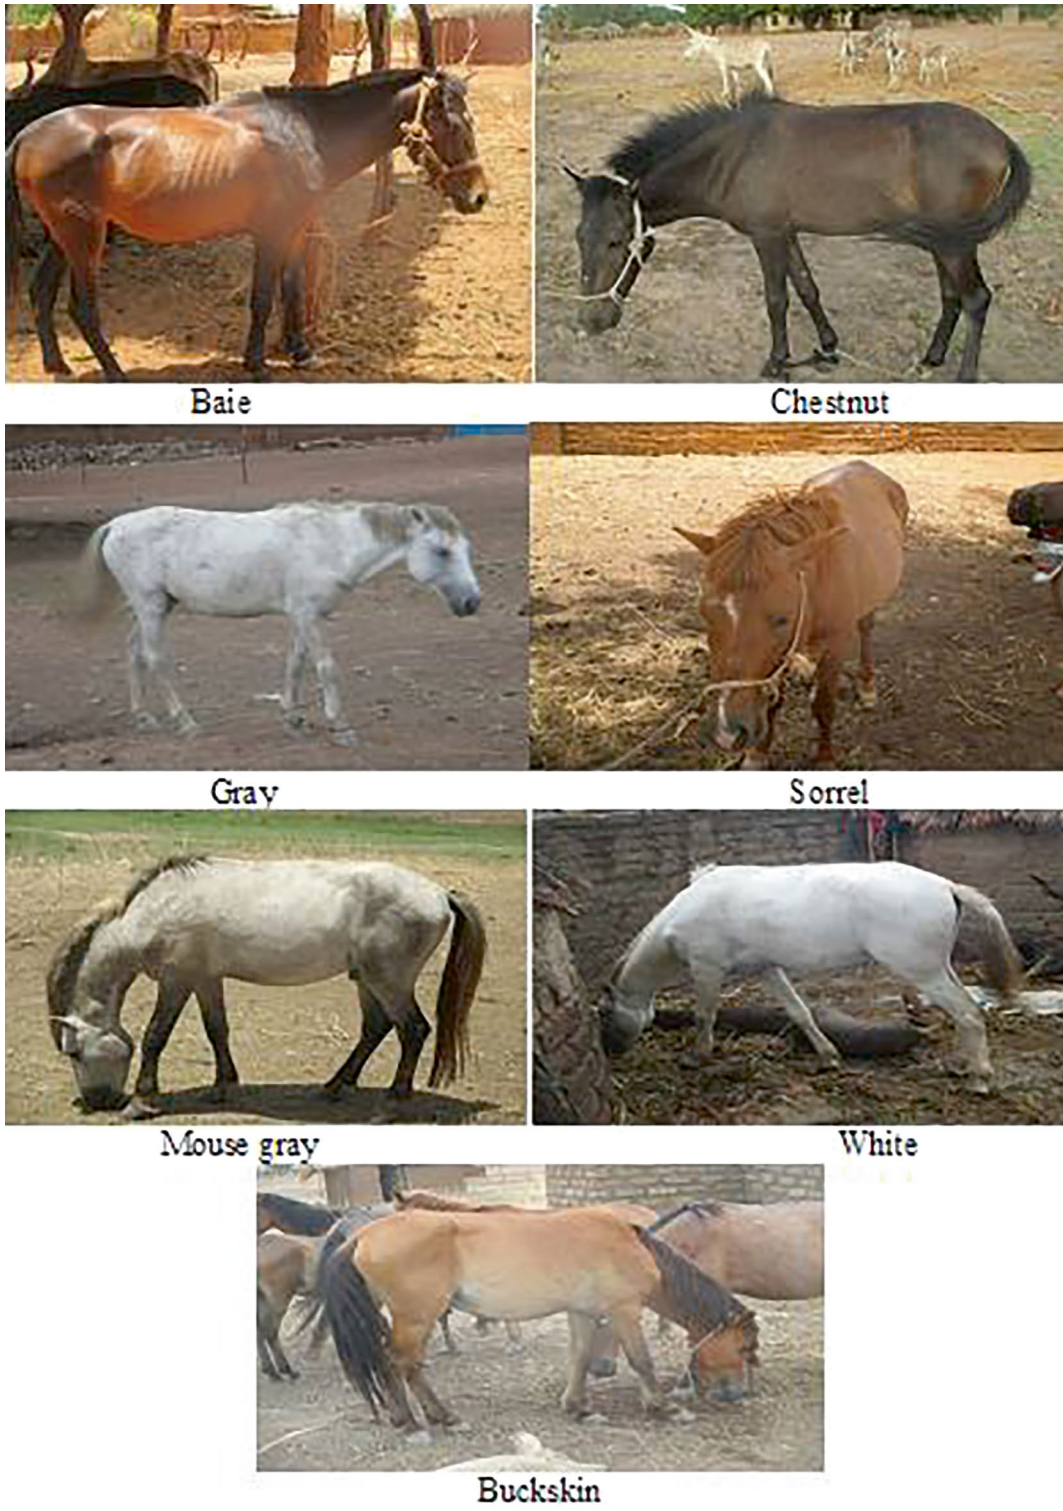

Fig. 11.17 Coat color diversity of the Kirdi pony in the Sudano-Sahelian region, Kabbia South-West of Chad. (Image credit: authors)

Fig. 11.18 Bélédougou horse used for carriage and pulling. (Image credit: Ferdinand Reus) (Claudot-Hawad 1988)

breed in Mauritania and Mali. In Mauritania, the Hodh horse is specific to the region of the same name, where it is raised by the Mechdoufs. The extinction threat level is unknown. The Hodh horse is a transborder local African breed with an unknown status (DAD-IS 2010).

Description and morphology: Hodh horse exhibits the Arab-Barb type (Doutressoulle 1952). However, CIRAD classifies it with the Barb (Meyer 2019), as does the DAD-IS database and the CAB International encyclopedia (Mason 1996; Porter et al. 2016; DAD-IS 2010), which group it among the "West African Barb" breeds. It stands at 1.45–1.48 m and weighs 325–375 kg (Doutressoulle 1952). Its coat is always gray (DAD-IS 2010).

A variety called Kreikibat is described as highly appreciated by the Moors for its gaits and endurance. This breed is perfectly adapted to the Sahelian North and is very sensitive to humidity (Doutressoulle 1952).

Uses: The Hodh horse breed is primarily ridden. The Mechdouf merchants' horses are partly responsible for the Senegalese horse breed called the River Horse (Ndiaye 1978), due to their trade along the banks of the Senegal River. Indeed, the expression "*Fas u nar u gor,*" which designates the River Horse, is very close to the Barb model in terms of conformation and size, and it means "Moorish stallion" (Ndiaye 1978).

Arewa

Origin and breed distribution: The Arewa (Fig. 11.2), a splendid horse from West Africa, is prevalent along the Niger River. It is believed to have descended from a Barb-Dongola cross. This breed is known by various names linked to the ethnic groups that possess it, including variants such as *Bagazan, Ganja, Manga, Gobir, Ader, Djerma* in the central Niger region, Nigeria, and Bornu in the East (DAD-IS 2010). In Mali, it takes on names like *Bandiagara* or *Gondo*, and in Burkina Faso, it is known as *Liptako* or *Djiligoldgi, Mossi*, and even Yagha in the North. In Chad, the Kadara results from a Barb-pony cross. The River or Narugor in Senegal originated from the crossing of local ponies with the Hodh breed. In Western Sudan, the Gharkawi or Kordofani breed emerged from crossbreeding Barb, Arabian, and Thoroughbred horses. The Foutanké or Fouta breed is a result of the Fleuve-M'Bayar cross (DAD-IS 2010).

The breed originates from a mixture of Barb and Dongola horse breeds. It developed during the years when Niger was a French colony, between 1922 and 1960. The French introduced Barb horses, which were better adapted to the hot climate than French horse breeds, to the region. They were crossbred with Dongola horses from Sudan and Eritrea. With the assistance of French breeders, a breed was developed to suit the work

demanded in the hot and dry climate of Niger (DAD-IS 2010). The breed has spread between Tombouctou and Say, as well as in central Niger. It is quite widespread, with over 200,000 of these horses recorded in Niger in 2017 (Dehoux et al. 1996). In 1951, Ian Lauder Mason characterized livestock and domestic horse breeds in West Africa, describing a breed of horses raised by the Djerma (Mason 1951).

In 2007, the FAO had no data on the potential threat level to the Djerma. The study conducted by Uppsala University, published in August 2010 for the FAO, reports the "Djerma" as a local African horse breed with an unknown threat level (Khadka 2010). The breed is indicated as not being endangered in the DAD-IS database (Dehoux et al. 1996). In 2018, 253,172 Aréwa horses were recorded throughout Niger, with this population growing (Dehoux et al. 1996).

Description and morphology: The Arewa horse belongs to the group of West African Barb or West African Dongola horses, often considered a variety of Dongola (Fig. 11.19). The build is light and fine. The head profile is convex (Rousseau 2014; Mason 1951). It is a mixture of Barb and degenerate Dongola, measuring 1.40 m to 1.48 m (Mason 1951). The Delachaux guide indicates an average height of 1.40 m (Rousseau 2014).

In 1949, a French colonial monograph mentions "the Djerma horse, raised along the Niger," described as "a small, common, and poorly balanced animal (Anonymous1949). The withers are marked. The croup is slightly sloping with a low-set tail (Rousseau 2014). The legs are slender, ending in small hooves. The mane and tail are fine, smooth, and not very full (Rousseau 2014). The coat is generally dark, bay, chestnut, or black, with white leg markings, but it can also be gray (Rousseau 2014; Mason 1951). These horses are particularly heat-resistant and frugal. They are strong, despite appearing weak due to their external appearance (Rousseau 2014).

Uses: They are used for all daily tasks, including riding, harness work, labor, leisure, and equestrian sports (Rousseau 2014).

Bobo

Origin and breed distribution: The breed probably owes its name to the Bobo-Dioulasso region. It is also known as "Bobodi" or (Dehoux et al. 1996) "Boboli" (Meyer 2019). These horses are relatively lesser-known. The Delachaux and Niestlé guide (2014), titled "Tous les chevaux du monde" and presented as comprehensive, does not mention the Bobo, Min(i)anka, or Koniakar breeds (Rousseau 2014). However, more reputable sources, such as the DAD-IS database and the CAB International encyclopedia, have entries for the Bobo breed (Mason 1996; Porter et al. 2016). Hendricks (2007) mentions the existence of this breed under the name "Bobo" but does not provide a description due to a lack of information (Hendricks 2007). The CIRAD animal science dictionary identifies Bobo ponies (Burkina Faso), Min(i)anka, and Koniakar (Mali) as belonging to the same type in a similar ecological niche, often interbred (Meyer 2019).

A group of Burkinabian researchers reports the presence of horse breeders in the urban area of Bobo-Dioulasso (Sanou et al. 2016), who are supplied with forage collected from natural environments to feed their animals. Horses are common on the streets of Ouagadougou (Manson et al. 2011).

This breed is listed as a local African horse breed with an unknown level of threat (Khadka 2010). The level of threat to the breed is also not provided in the DAD-IS database, which lacks population data (Dehoux et al. 1996).

Description and morphology: The Bobo ponies exhibit the West African "Barb pony" type (Mason 1996; Porter et al. 2016) (Fig. 11.20). The animals are reputed to be well-built, with CIRAD attributing a height of 1.20–1.35 m for Minianka ponies from Mali, weighing around 200 kg. The Koniakar from the Kayes region is reported to be 1.35–1.40 m tall, weighing approximately 250 kg (Meyer 2019). These ponies are likely resistant to Trypanosomiasis (Meyer 2019).

Uses: These ponies are used for riding.

Fig. 11.19 Arewa stallion. (Edward and Bukola 2023)

The M'bayar Pony

Origin and breed distribution: The name of this breed can also be spelled as *Mbayar* or *M'bayar (*Rousseau 2014*)*. Due to limited documentation on the origins of Senegalese horses (Rischkowsky and Pilling 2007), it is postulated that the *M'Bayar* is an ancient indigenous breed, possibly descending from Barb horses that came from the Maghreb region (ISRA 2003). Historically, this breed was primarily used for the military cavalry of ancient traditional kingdoms. In the twentieth century, the M'Bayar was influenced by Barb horses imported from Mali, Mauritania, and Morocco, as well as Arabian and Anglo-Arabian horses from the Dahra Zootechnical Research Center (ISRA 2003).

In 1996, Senegal had approximately 400,000 horses of all breeds, the largest horse population among all West African countries (ISRA 2003). The M'Bayar is the most common of the four

Senegalese horse breeds, with the others being *M'Par, Fleuve*, and *Foutanké* (ISRA 2003; https://horsebreedslist.com/fleuve/). It is considered a locally adapted breed in Senegal, particularly in the Baol region, and its population size is unknown. There is no available data regarding the threat level to the *M'Bayar* breed. In both 2007 and 2010, FAO did not have information related to the conservation of this breed (DAD-IS 2010; Khadka 2010). The M'Bayar is commonly found in the Diourbel and the Wolof regions of Cayor, Baol, Waalo, and Djolof. In the Sine Saloum region, herds of these horses live semi-freely in the plains (Rousseau 2014).

Description and morphology: The average height of the M'Bayar ranges from 1.34 m to 1.44 m (ISRA 2003), with the Delachaux guide indicating a range of 1.37 m to 1.45 m (Rousseau 2014). DAD-IS database records an average height of 1.37 m among males (Dehoux et al. 1996). This size places it closer to a pony. CAB International's encyclopedia (2016) classifies this breed as part of the West African pony group (Mason 1996; Porter et al. 2016). It is a compact and sturdy small horse with a broad chest and a short neck. Its legs are robust but often exhibit cow hocks and other characteristics considered as faults (Rousseau 2014; ISRA 2003).

The coat color is usually solid, with bay being the predominant color, followed by chestnut. Gray and roan coats are also common (DAD-IS 2010; Rousseau 2014; ISRA 2003). The M'Bayar is known for its calm and docile temperament, hardiness, and endurance (ISRA 2003). It is highly resistant to the climatic conditions of the Sahel, which is characterized by dry and hot weather (Rousseau 2014). The breeding of M'Bayar horses in Senegal is managed by the Senegalese Agricultural Research Institute (ISRA) (https://horsebreedslist.com/fleuve/).

Uses: In Senegal, the M'Bayar is used for riding (Mason 1996; Porter et al. 2016), as well as for draft work, such as pulling carriages or agricultural plowing (DAD-IS 2010) (Fig. 11.21). It plays a significant role in the daily life of Senegalese people, both in rural areas and major cities like Dakar, Saint-Louis, Kaolack, etc. It is also used for horse racing in racetracks (ISRA 2003). The M'Bayar horse is often crossed with Arabian Thoroughbreds by breeders in Senegalese studs to produce crosses for horse racing. The M'Bayar has contributed to the development of the Foutanké breed through crossbreeding with the Fleuve breed (Mason 1996; Porter et al. 2016).

The "Fleuve"

Origin and breed distribution: According to the DAD-IS database and the Delachaux guide, these horses are known as "Naru Gor" (DAD-IS 2010) or "narugor" (Rousseau 2014) in Wolof. However, the CAB International dictionary (2016) indicates that "narugor" is the Wolof name for the "Foutanké" breed (Mason 1996; Porter et al. 2016). The name "Cheval du Fleuve," in French, derives from the word "Fleuve," meaning "river."The breed originates from a cross between the *Barb* horses from Hodh or Kayes and the local Senegalese pony population (Mason 1996; Porter et al. 2016; Dehoux et al. 1996). However, recent crossbreeding among Senegalese horses has made the characterization of breeds difficult (Rousseau 2014).

The breed is specific to Senegal, where it is considered "locally adapted." According to Khadka (2010), the "Fleuve" is a local African breed, but the level of threat to its survival is unknown (Khadka 2010). The DAD-IS database from 2018 also lacks information on population numbers or threat levels (Dehoux et al. 1996).

Description and morphology: The average height of the "Fleuve" is 1.40 m, with a median weight of 325 kilograms (Dehoux et al. 1996). Others suggest the height ranges from 1.40 m to 1.50 m at the withers (Rousseau 2014). They are lightweight riding horses (Dehoux et al. 1996). They are very close to the "Foutanké" but slightly finer (Ndiaye 1978). They have a relatively fine head, a rather narrow chest, a croup with a sloping shape, and slender, long limbs (Rousseau 2014) (Fig. 11.22). Their coat comes in various shades of gray (Rousseau 2014; Dehoux et al. 1996). These horses are known for being lively and energetic, well-suited to the local climate (Rousseau 2014). The management of the breed is overseen by ISRA and *Laboratoire National de*

Fig. 11.21 M'bayar horse served for light draft in Pikine, Sénégal. (Source: Lejosne 2023)

Fig. 11.22 Fleuve horse breed from Sénégal in West Africa

l'Elevage et de Recherches Vétérinaires (LNERV) (Dehoux et al. 1996; https://horsebreedslist.com/fleuve/).

Uses: These horses are used for riding and driving (Rousseau 2014).

Foutanke

Origin and breed distribution: Foutanké is the local name of the breed, also known as "Narougor" according to CAB International (Mason 1996; Porter et al. 2016). There is no written documentation regarding the history of horse breeding in Senegal (Rischkowsky and Pilling 2007). The Foutanké is the result of a cross between a stallion from the Fleuve breed and an M'Bayar mare (Ndiaye 1978; Mason 1996; Porter et al. 2016; Rousseau 2014; Lejosne 2023). CAB International classifies it among the Barb-type ponies originating from West Africa, in the group of "West African Barbs" (Mason 1996; Porter et al. 2016). The Foutankébreed is specific to Senegal (Rousseau 2014). The Foutanké is raised in the Sine-Saloum region (Doutressoulle 1947). In 2007,

the FAO had no data on the potential threat level to the Foutanké (https://experiencingnaija.com/what-did-you-know-about-hausa-fulani-wedding/). Khadka (2010) reported the Fouta as a local African breed with an unknown threat level (Khadka 2010). Its threat level is also unknown in the DAD-IS database from 2018 (Dehoux et al. 1996).

Description and morphology: According to Larrat (1947) there are three Senegalese horse breeds: M'Bayar, Foutanké, and M'par. The Foutanké was described as resulting from an attempt to transform the M'Bayar through crossbreeding to increase its size; the results of these crossbreeding are not always very successful, with many horses from these crosses being narrow or greyhound-like (Rischkowsky and Pilling 2007). According to him, the best Foutankés measure between 1.38 m and 1.43 m. According to Rousseau (2014), the Foutanké measures from 1.35 m to 1.50 m at the withers (Rousseau 2014). Measurements taken by Larrat (1947) gave an average height of 1.41 m, describing it as a proportionate horse (Rischkowsky and Pilling 2007). It closely resembles the horse of the Fleuve but is coarser. The most common coat colors are gray and chestnut (Rousseau 2014). These horses are known for being rugged and resilient (Fig. 11.23). The Foutanké is one of the four recognized horse reeds in Senegal, based on Larrat's description (Rischkowsky and Pilling 2007), but extensive crossbreeding among Senegalese horses makes the concept of a "pure breed" difficult to apply (https://horsebreedslist.com/fleuve/).

Uses: These horses are used for riding, driving, and agricultural work (Rousseau 2014). They are particularly sought after for racing (ISRA 2003) (Fig. 11.23).

The M'Par

Origin and breed distribution: The origins of horses in Senegal are not documented. The M'Par could be an indigenous breed with ancient origins in the region (Rousseau 2014). Others, like Larrat (1947), view the horses in Senegal as descendants of Barb horses originating from North Africa (Rischkowsky and Pilling 2007). Regardless, its original homeland is the Cayor region in Senegal, West Africa, which is why it is also known as the "Cayor pony". It is described as a locally adapted horse breed in Senegal, specific to the former Cayor region, with unknown population numbers (Dehoux et al. 1996). The region of origin actually admitted is Louga and Thiès. In 2007, the FAO had no data to estimate the conservation status of the M'Par breed, but agreed it is likely a local breed (https://experiencingnaija.com/what-did-you-know-about-hausa-fulani-wedding/).

Description and morphology: The M'Par is the smallest of the four Senegalese horse breeds (Rischkowsky and Pilling 2007), with the others being the M'Bayar, the Fleuve, and the Foutanké (https://horsebreedslist.com/fleuve/). The average height of males is approximately 1.30 m (Dehoux et al. 1996), with a general range of 1.25–1.35 m (Ndiaye 1978; Rousseau 2014). In terms of morphology, the M'Par resembles the Barb horse (Mason 1996; Porter et al. 2016), although it is generally considered to have poor conformation, including a heavy head, a long back, thin legs, a flat chest, and often defective leg conformation (Rischkowsky and Pilling 2007). This morphology may result from breeding and feeding conditions, as better-nourished horses tend to have more harmonious conformation (Rousseau 2014).

The coat of the M'Par is typically bay, in various shades, or chestnut, but it can vary. In terms of temperament and care, the M'Par is known for exceptional endurance and hardiness (Dehoux et al. 1996; Rischkowsky and Pilling 2007).

Uses: Horses play a significant role in the social and economic life of Senegal. The M'Par is used as a draft horse, particularly in agriculture (Ndiaye 1978) (Rousseau 2014);. Due to its small size, it can only pull light carts and carriages (Ndiaye 1978). It could also be used as a teaching horse for young riders (Rousseau 2014).

The Bagzan

Origin, naming, and breed distribution: The Bagzan is also known by the names "Berrezem", "Baguezzan" (Doutressoulle 1947), "Baguezane," or "Kinaboutout," (Epstein 1971). The name "Bagzan" refers to both this specific horse breed

Fig. 11.23 A Foutanke or Narougor horse in Pikine, Sénégal. (Lejosne 2023)

and the winged horse in Tuareg mythology (Bernus 2002). The Bagzan is considered mythical and legendary, and only a good Tuareg is deemed worthy of riding it, as opposed to the common and less valuable horse, known as the efàkre (Baroin and Boutrais 1999; Bernus 1995). The DAD-IS database includes the "Bagazan" in the group of the national horse breed of Niger, known as Aréwa (Benecke 2006). However, it strongly resembles the Arabian horse (Dehoux et al. 1996).

Bagzan horse breed has its origins in the Bagzane Mountains of Africadate back to the 1850s. It explores the legendary origins of the breed, including stories of a stallion from Istanbul and Arabian horses brought to the mountains (Haddad et al. 2014). There are various oral traditions surrounding the breed's creation, including its use by the Kel Gress tribe in the eighteenth century. Despite its legendary status, the Bagzan breed faced population challenges due to historical conflicts in the region. This breed is known for its elegance, endurance, and ability to navigate rocky terrain, making it highly regarded among the Tuareg people (Hamami 1989). The text also mentions a French military officer's documentation of these features and a colonial veterinarian's description of the breed in 1947 (Doutressoulle 1947).

Description and morphology: The Bagzan is a small, square-built horse, standing at approximately 1.40 m, known for its exceptional elegance (Doutressoulle 1947). It has a short and square head with a straight profile, a broad forehead, expressive eyes, and short, mobile ears (Doutressoulle 1947). The neck is slightly arched and covered with a luxurious mane, with occasionally wavy strands (Anthony 1996). The back is short and straight, providing good support (Doutressoulle 1947). The croup is round and horizontal, resembling an apple, with a tail set high. The chest is broad, the ribs are rounded, and the flanks are short. The limbs are slender, even delicate, with a cannon circumference of less than 18 cm, but they are sturdy (Anthony 1996). The hooves are tough (Doutressoulle 1947).

The coat of the Bagzan is always gray (Epstein 1971; Doutressoulle 1947). This breed is renowned for its simplicity, speed, endurance, and impressive, elongated gaits (Doutressoulle 1947). It is said to be able to go without water for three days. The Tuareg people feed these horses with millet and camel milk (Epstein 1971).

Uses: The Bagzan has significant use among the Tuaregs, especially for long journeys across

rocky terrains (Haddad et al. 2014). However, its ownership is reserved for the wealthiest Tuaregs due to the need to provide it with supplementary nutrition (Doutressoulle 1947). The Bagzan is mentioned in poems and narratives where it symbolizes nobility (Haddad et al. 2014). Traditional battle accounts attribute numerous feats to its supernatural speed and the ability to safely bring back its wounded master (Haddad et al. 2014). It is also said to have the ability to understand human language, to weep, and to refuse food if insulted. These traditional poems always mention the horse by name. Bagzan horses are traditionally buried after their death, and the burial sites are known to Tuareg riders (Haddad et al. 2014).

The Mogods Pony

Origin, naming, and breed distribution: The origins of the Mogods pony remain unclear, although research is ongoing (Chabchoub et al. 2006). According to one hypothesis, the Mogods pony may be a variant of the Barb, Arab-Barb, or Arab horse. Another hypothesis considered it to be a breed distinct from the Barb and the Arabian horses (Sebbag 2002). For others, it could be a primitive indigenous breed whose owners, fleeing invasions, took refuge in the mountains. It is believed that the breed became adapted to mountainous regions during this time. The breed is native to the extreme northwest of Tunisia (Chabchoub et al. 2006; Dehoux et al. 1996). The Mogods region is its cradle. Mogod ponies can also be found in the regions of Amdoun, Héllil Mogod, and Nefza (Chabchoub et al. 2006). These areas are characterized by rugged terrain, cork oak forests, and summer drought, all of which have shaped the pony's morphology and character.

The breeding of this pony breed flourished in the twentieth century particularly in the early twentieth century. The Mogods pony was highly prized for equestrian sports, such as polo. According to the Bulletin of Agriculture and Trade of Tunisia, published in 1903, approximately 500 ponies were exported annually to Italy, Malta, France, and England. It is reported that Lord Mountbatten, the last Viceroy of India, purchased a batch for his polo team. The Tunisian administration decided in August 1902 to manage this breed through a specific studbook. However, World War I put an end to these efforts. The production of the pony significantly declined after the end of World War II, mainly due to the mechanization of agriculture (Fondation Nationale d'Amélioration de la Race Chevaline (FNARC) 1988). To prevent the breed's extinction, Tunisian authorities entrusted the management of this breed to the National Foundation for the Improvement of Horse Breeds, a public institution under the Ministry of Agriculture and National Federation for the Improvement of the Horse Breed (FNARC) (SADA 2006). Its population was estimated at around one thousand individuals in 2002 (Chabchoub et al. 2006; Fondation Nationale d'Amélioration de la Race Chevaline(FNARC) 1988). There is no recorded population data in the DAD-IS database (Dehoux et al. 1996); the breed requires an inventory and conservation measures (Rousseau 2014).

Description and morphology: The Mogods pony measures between 1.20 m and 1.45 m according to reported studies (Chabchoub et al. 2006; Rousseau 2014). It closely resembles the Barb horse with a well-proportioned body and pronounced muscles (Rousseau 2014). It has a short and strong neck, a straight back, and short and lean limbs. Its chest is wide and deep, and it has an expressive head. The pony has very regular conformation and hard hooves, eliminating the need for shoeing (Fondation Nationale d'Amélioration de la Race Chevaline(FNARC) 1988) (Fig. 11.24).

Some studies suggest that the Mogod pony's morphology is more similar to that of a horse rather than a pony (Fondation Nationale d'Amélioration de la Race Chevaline(FNARC) 1988). Its eyes, withers, croup, and loins strongly resemble those of the Barb horse. Some of its morphological characteristics do not correspond to those of a pony: it is taller than long, with a cannon bone length greater than that of the Barb. The most common coat colors are bay, chestnut, and gray. Primitive markings, such as stripes, are possible. The Mogods pony is a robust pony accustomed to harsh living conditions. It is a mountain breed, very sure-footed and with a

Fig. 11.24 Mogods pony. (Chabchoub et al. 2006)

calm yet energetic temperament. It possesses great working capacity and is often handled by children or the elderly.

Uses: The Mogods pony is highly versatile. In its original mountainous region, it is used as a pack animal for carrying water or goods. It is also employed as a means of transportation, often ridden bareback and without a bit (Chabchoub et al. 2006) (Fig. 11.24). However, due to increasing mechanization observed even in the most remote rural areas, it is becoming less commonly used for these purposes.

With the renewed interest it has gained, a return to recreational or sports use, as it existed in the early twentieth century, is possible. The Mogods pony could be a suitable partner for activities such as driving, trekking, and more. Because of its calm and docile nature, it can serve as an excellent teaching pony (Chabchoub et al. 2006).

The Cape Horse or Boerperd

Origin, naming, and breed distribution: The Cape Horse is also known as Hantam and Boer (DAD-IS 2010). It was one of the first horse breeds developed in South Africa (Cothran and Van Dyk 1998), accompanying European colonization in its history and development (Mason 1996; Porter et al. 2016). It never had a stud book and originally formed a unique strain with the Basuto (DAD-IS 2010), both descended from horses imported from the Indonesian islands (Mason 1996; Porter et al. 2016).

The Cape Horse resulted from multiple influences of successive waves of horse importations to South Africa. Initially, there were Oriental horses between 1652 and 1778, likely of Arab-Barb and Persian origin (Mason 1996; Porter et al. 2016), followed by Criollos in 1778, Thoroughbreds from 1782 to 1860, and Hackneys from 1860 to 1891 (DAD-IS 2010). The blending of these imported breeds formed the Cape Horse in the early 1800s. Starting in the 1820s, it was mainly influenced by the importation of Arabian and Thoroughbred horses (Mason 1996; Porter et al. 2016). Despite the loss of many Cape horses during the Great Trek, the Cape Horse breed persisted locally in its original form (Cothran and Van Dyk 1998). Breeding horses allowed white European settlers to differentiate themselves from indigenous people, reaffirming their European identity (Bankoff and Swart 2008).

The Cape Horse nearly went extinct in the early twentieth century due to crossbreeding, epidemics in the late nineteenth century, and the Anglo-Boer Wars of 1880 and 1899 (Mason 1996; Porter et al. 2016). During the Second Anglo-Boer War, the British captured or eliminated Cape Horses because they were naturally resistant to African equine diseases and could

serve as weapons of war Wessels (1991). Only a handful of these horses remained in the Cape region, where they were eventually crossed with other breeds. The South African Department of Agriculture estimated the population of the Cape Horse to be around 1900 (Cothran and Van Dyk 1998).

The South African horse breed nomenclature becomes even more perplexing due to the activities of a group of breeders primarily based in the Cape Province. Beginning in the 1950s, these breeders established the SA Riding Horse Breeders' Society, with the aim of enhancing the existing Boerperd breed by introducing American Saddlebred and Morgan stallions (Kaplan 1974). Over the years, they diligently pursued recognition from both the Department of Agriculture and the South African Stud Book Association. Their efforts eventually bore fruit in May 1984 when the Cape Boerperd Breeders' Association was officially recognized by the Minister for Agriculture, and they received a certificate of incorporation from the South African Stud Book Association (Mason 1996; Porter et al. 2016; Cothran and Van Dyk 1998; FAO 2002).

For 130 years, the Cape Horse was widely exported throughout the British colonial empire, mostly for military use (Cothran and Van Dyk 1998). Like other horse breeds developed by settlers, it embodied local identity and accompanied the rise of nationalism (Bankoff and Swart 2008). In comparison to the English Thoroughbred, the Cape Horse was not considered a high-status mount but represented the pride of white South African colonists (Bankoff and Swart 2008). It is listed as an extinct local South African and African horse breed (Khadka 2010; Dehoux et al. 1996).

Description and morphology: The Cape Horse has a light build. While its exact morphology is not known, it likely does not resemble a pony (Hendricks 2007). Natural selection for adaptation to the climate and human selective breeding, favoring working animals with a calm disposition, resulted in a uniform breed with its characteristics (Cothran and Van Dyk 1998). The Cape Horse is known for its gentleness (Cothran and Van Dyk 1998).

Uses: The Cape Horse served as a working mount in farming (Dehoux et al. 1996) and a military mount when needed (Mason 1996; Porter et al. 2016). It was the first horse breed introduced to Australia. The Cape Horse also contributed to the development of the Boer du Cap, South African Boer, Basuto, Nooitgedacht, Namaqua (Dehoux et al. 1996), and Carrossier du Cap breeds (Kreuz 1958). It gained a strong reputation during the Great Trek, accompanying Boer farmers' colonization, earning it the name Boerperd (Cothran and Van Dyk 1998).

Boer du Capor Kaapse boerperd

Origin, naming, and breed distribution: The correct spelling of the name of this horse breed uses an initial capital letter in the word "Boer," as this breed is named after the Boer ethnic group (Giammatteo 2019).

Derived from the Cape Horse (which is probably not a pony) (Hendricks 2007), the Boer du Cap is an "improved" version of the latter, originally selected for agricultural work (Mason 1996; Porter et al. 2016). Its ancestors were crossed with Hackneys and Saddlebreds (Rousseau 2014). During the second half of the nineteenth century, it was influenced by the Frison du Hackney, Norfolk Trotter, and the Cleveland Bay (Hendricks 2007).

An association of breeders, the Kaapse Boerperd Breeders Society of South Africa, was established in 1948 (FAO 2002). Disagreements among South African breeders led to a split, creating two associations with different breeding objectives. The creation of the Boerperd Breeders' Society of South Africa resulted in crossbreeding the remaining population of historical Boer ponies with Saddlebreds, Hackneys, Thoroughbreds, and Arabians (Hendricks 2007). In 1993, recognizing the risk of losing the breed's identity, breeders reintroduced eight crossbred stallions to reinforce the distinctive characteristics of the Boer du Cap (FAO 2016 2003). The breed remains under selection, with its studbook only being closed in 1999.

The breed is native to South Africa. Rousseau (2014) and Boerperd Breeder's Society of South

Africa indicate a population of 1924 individuals in 2013 (Rousseau 2014).

Description and morphology: Rousseau (2014) reported the height as ranging from 1.42 m to 1.62 m with a long head (Rousseau 2014). It was described as dry, finely chiseled, with a straight profile, large-spaced eyes, moderately long ears, and a refined throat latch (Hendricks 2007). The neck is carried high, long, and slightly arched, with a sloping and muscular shoulder (Rousseau 2014; Hendricks 2007). The back is short, the body is deep, and the legs are strong, with wide joints (Mason 1996; Porter et al. 2016). The coat is generally bay (Mason 1996; Porter et al. 2016). The breed can exhibit additional gaits (Rousseau 2014). These horses are known for their endurance and sure-footedness (FAO 2002).

Uses: Widely associated with agricultural work and military actions of the Afrikaners, it is now extinct in its original form due to extensive crossbreeding (Fig. 11.25). It has contributed to the development of breeds like the Carrossier du Cap, Boer du Cap, South African Boer, Nooitgedacht, and Namaqua.

Boer Sud-Africain or Suid-Afrikaanse Boerperd

Origin, naming, and breed distribution: In Afrikaans, "boerperd" means "farmer's horse," but it can also be a reference to the Afrikaners. This breed descends from the first horses introduced to South Africa in 1652 from Java, likely of Arab-Barb type (Mason 1996; Porter et al. 2016). Later, Mongolian horses influenced this population (Mason 1996; Porter et al. 2016). The Boer shares common origins with the Basuto, as both were selected from the Cape Horse during the nineteenth century. However, the Boer receives bloodline contributions from Flemish horses, Hackneys, and Cleveland Bays. Its living conditions are not as harsh as those of the Basuto; it is a larger breed with a more powerful conformation. During the Second Anglo-Boer War, the great mobility of this small horse helped the Boers move and resist the British Empire for 3 years.

The Kaapse Boerperd Breeders Society of South Africa, an association of breeders, was established in 1948 (FAO 2002). The breed saw its first declines in the 1950s. A new association, the Boerperd Society of South Africa, was formed in 1973. It changed its name to become the Historiese Boerperd Breeders Society in 1977, then the South African Boerperd in 1998 (SASB 2003). The Historiese Boerperd was officially recognized by the South African Department of Agriculture in 1996 (SASB 2003). This association is a member of the SA Stud Book Association (Promerová et al. 2014). South African Boerperds live in isolated herds in the Southeastern Transvaal, Northern Natal, Eastern Free State, and Northeastern Cape Province.

Description and morphology: It typically measures between 1.30 m and 1.50 m. The most common coat colors are black, chestnut, bay, gray, roan, dun, and palomino. The South African Boerperd has been the subject of a study to determine the presence of the DMRT3 gene mutation responsible for additional gaits. The study of 20 individuals detected the presence of this mutation in 15% of them, without confirmation of the existence of horses with additional gaits within the breed. However, there is no specific distinction made between South African Boerperd and Boer du Cap in this context (Promerová et al. 2014).

Uses: The Boer is the origin of the creation of the Calvinia horse.

The Basuto Pony

Origin, naming, and breed distribution: The Basotho or Basuto is a pony breed originating from Lesotho (formerly Basutoland) and South Africa. The breed was developed in Lesotho, a landlocked country in South Africa (Mason 1996; Porter et al. 2016). Initially, its history was closely linked to that of the Cape Horse (Dehoux et al. 1996), which, in turn, had diverse origins, including Javanese, European, and possibly Mongolian horses (Mason 1996; Porter et al. 2016). These animals were repeatedly crossbred in the eighteenth century with Arabians, Thoroughbreds, and Persian horses (Mason 1996; Porter et al. 2016). The Basuto's origins date back to approximately 1825 when it was

Fig. 11.25 Cape Boerperd mares and foals at pasture (Van der Merwe and Martin 2002)**.** (Image credit: Van der Merwe and Martin 2002)

introduced to Basutoland by the Zulu chief Msosesha (Dehoux et al. 1996). The Basuto pony has maintained its small number and has adapted to its environment, situated at an altitude of about 1400 m. This breed is currently endangered. The Basuto pony was listed as distinct in the DAD-IS (2006) list. It classified the Basotho as an extinct local African breed (Khadka 2010). Furthermore, the 2012 edition of Equine Science categorizes it among the relatively unknown pony breeds at an international level (Parker 2012).

Description and morphology: The Basuto pony has an average height of 1.42 m (Rousseau 2014), and is generally less than 1.47 m (Mason 1996; Porter et al. 2016). It is slender yet agile, exceptionally resilient, robust, enduring, and brave (Fig. 11.26). This breed can carry heavy loads over long distances. Its upbringing has made it rugged and thrifty, with extremely sure-footed hooves. The coat of the Basuto pony is often chestnut or bay, occasionally gray. White markings are infrequent and limited. It possesses a refined head, carried by a long and often arched neck (swan neck), sparse manes, powerful hindquarters, short and sturdy limbs, and tough hooves.

The Basuto pony has been the subject of a study aimed at determining the presence of the DMRT3 gene mutation responsible for additional gaits. The study, which involved 30 subjects, found the presence of this mutation in 6.7% of them, although there was no confirmation of the existence of horses with extra gaits within the breed (Promerová et al. 2014).

Uses: The Basuto pony primarily serves as a working horse (Dehoux et al. 1996), but it is also used for pack and light draft work (Mason 1996; Porter et al. 2016). This pony has participated in various wars, including the Second Boer War, where it gained recognition as a fast and agile mount used by Boer farmers. Today, it is sought after as a leisure and sport riding horse, popular for hiking, polo, and occasionally racing. It has also given rise to the Nooitgedacht breed.

The Nooitgedacht

Origin, naming, and breed distribution: The Nooitgedacht (Afrikaans: *Nooitgedachter*) is a breed of small riding horses originating from Southern Africa. It is a rare breed primarily used for leisure riding. In Afrikaans, these horses are called *Nooitgedachter* or *Nooitgedachtperd* (DAD-IS 2010). The breed's origins can be traced back to the characterization of South African horses, initiated in the late 1940s (NHBS 2021). In December 1951, the Basuto pony was selected by the South African Department of Agriculture for its qualities of adaptability and hardiness (NHBS 2021). The Nooitgedacht is a breed artificially created at the Nooitgedacht (which translates to "never imagined") experimental farm in the southeastern Transvaal from the Basuto Pony

Fig. 11.26 Basuto pony (Van der Merwe and Martin 2002). (Image credit: Martin J. in Van der Merwe and Martin 2002)

(Rebts 2017). Crossbreeding was employed to create an animal suitable for local climate conditions. The founding stallion of the Nooitgedacht, Vonk, is originally a Basuto and is the ancestor of all current Nooitgedacht horses (Rebts 2017). Crossbreeding with Arab horses, part-bred Arab horses, and Boer ponies was also practiced. A significant influence on the breed's development was the Nooitgedacht stallion named Mac, born in 1958.

An association for the breed was established in 1968, but Nooitgedacht was only officially recognized in South Africa 8 years later, in 1976. In March 1977, the Nooitgedacht farm organized a public animal sale, contributing to the breed's spread. The breed's selection was entirely entrusted to the breeders' association, which had 60 members by 1979 (Rebts 2017).

With only 400 individuals registered, the breed is considered rare. A study conducted by Uppsala University in August 2010, in collaboration with the FAO, categorizes the Nooitgedacht as a regional transboundary breed of Africa in danger of extinction.

Description and morphology: The Nooitgedacht is an elegant yet robust small riding horse with quality bone structure (Fig. 11.27). The height typically ranges from 1.38 m to 1.63 m. They have strong hooves that generally do not require shoeing. Their back is short, and they have well-formed shoulders (Rebts 2017). They typically have gray, bay, chestnut, or roan coats, with piebald and skewbald patterns being prohibited. Nooitgedacht horses are hardy and low-maintenance. They are intelligent and have excellent temperaments, showing affection toward people (Rebts 2017). A study on the presence of the DMRT3 gene mutation based on 14 subjects found the mutation in 21.4% of the horses. This confirms the existence of horses with additional gaits within the breed (Promerová et al. 2014).

Uses: These horses are appreciated for their endurance as riding horses and are used for show jumping, gymkhana, and leisure riding. They excel in polo and are often employed in reserves for patrolling in dangerous areas (Rebts 2017).

The Vlaamperd

Origin, naming, and breed distribution: The Afrikaans name "Vlaamperd" translates to "Flemish Horse" in French (Mason 1996; Porter et al. 2016; Dehoux et al. 1996). It is essential not to confuse this breed with the European Flemish horse (Vlaams Paard) (Rousseau 2014), as they have different origins and uses. In South Africa, the term "Flemish" was applied to any horse imported from the Netherlands or Flanders during a period when the export of Dutch horses was

Fig. 11.27 The South African Nooitgedacht stallion named Mac. (FAO 2002)In 1958, the birth of the stallion Mac marked a pivotal moment in the development of the Nooitgedacht horse breed. Mac exemplified the ideal general-purpose horse sought by project managers, displaying key physical traits such as a strong shoulder, well-muscled back, and robust legs with hard hooves. Additionally, Mac embodied the distinctive characteristics of the Nooitgedacht breed, with his small pointed ears, pronounced brows, and straight to slightly concave profile. This iconic horse left a lasting legacy in the breed's evolution (Photo: Landbouweekblad)

prohibited, regardless of the actual genetic origin of the animals (Mason 1996; Porter et al. 2016).

The South African Vlaamperd is the result of crossbreeding with Frisian horses imported into the country in the early twentieth century. These Frisians were crossed with the local horse population, primarily composed of the Cape Horse (Mason 1996; Porter et al. 2016), as well as Thoroughbreds, Hackneys, and Cleveland Bays (Dehoux et al. 1996). An Oriental Frisian stallion known as Kemp also had a significant influence on the modern Vlaamperd (SAVBS 2019).

The breed's studbook was established in 1983 (Dehoux et al. 1996), coinciding with the founding of the SA Vlaamperd Breeders Society in Bloemfontein (SAVBS 2019). By 1992, there were only 165 registered Vlaamperd horses, including 65 mares in the studbook (Dehoux et al. 1996). In 1999, the population had likely increased, estimated to be between 100 and 1000 individuals (Dehoux et al. 1996).

The Vlaamperd is considered a local South African breed (Dehoux et al. 1996), predominantly found in the Western Cape region (Mason 1996; Porter et al. 2016; Rousseau 2014). In the past, it was close to extinction (Mason 1996; Porter et al. 2016; Hendricks 2007) but was recognized as one of the locally developed exotic horse breeds by the South African Department of Agriculture in June 2006 (Cothran and Van Dyk 1998). The Vlaamperd is not mentioned in the study conducted by Rupak Khadka from Uppsala University, published in August 2010 for the FAO (Khadka 2010). According to the Delachaux guide, the breed still exists but in very limited numbers, with approximately 200 individuals in 2013 (Rousseau 2014).

Description and morphology: The Vlaamperd's height ranges from approximately 1.47–1.57 m (Mason 1996; Porter et al. 2016), with an average of 1.54 m (Dehoux et al. 1996). It has a lightweight (Mason 1996; Porter et al. 2016; Dehoux et al. 1996), medium-sized build and is morphologically similar to the Frisian horse that influenced its development, albeit slightly finer (Rousseau 2014). The head is mod-

erately long with a straight profilewhile the neck is carried high and features a characteristic arch. The croup is round, and the legs are long (Rousseau 2014). The breed's mane and tail are abundant, as are the feathering on its lower legs (Rousseau 2014) (Fig. 11.28).

The Vlaamperd's coat is typically black (Mason 1996; Porter et al. 2016; Dehoux et al. 1996), although a dark bay is also accepted for mares (Rousseau 2014; SAVBS 2019). Some horses may exhibit bay-brown shading in their mane (Mason 1996; Porter et al. 2016) (Fig. 11.28).

The Vlaamperd is known for its power, cooperative nature, and elevated gaits (Rousseau 2014) (Fig. 11.28). The breed's selection is overseen nationally by the South African Stud Book and Livestock Improvement Association (SASBLIA) and is particularly supported by the Suid Afrikaanse Vlaamperdtelersgenootskap (Dehoux et al. 1996; SAVBS 2019).

Uses: The Vlaamperd is primarily used for harness (Dehoux et al. 1996), where its spectacular gaits make it highly successful in various forms of carriage competitions (Rousseau 2014; SAVBS 2019). However, it can also be ridden with success and has gained popularity in dressage (Mason 1996; Porter et al. 2016).

The Calvinia

Origin, naming, and breed distribution: The Calvinia horse was created by European settlers in South Africa's Calvinia region, using the Cape Horse, Thoroughbred, Hackney, and Cleveland Bay (Mason 1996; Porter et al. 2016; Dehoux et al. 1996), after the Great Trek. A stud farm was indeed established in the town of Calvinia (Hendricks 2007), supplying the surrounding regions with selected specimens of Cape Horses, known as "Hantam horses". It is one of the two notable horse breeds selected at that time by Boer farmers, along with the Cape Trotter (Kreuz 1958), resulting from the last influences on the local strain of the Cape Horse (Mason 1996; Porter et al. 2016).

Its extinction date is not specified (Mason 1996; Porter et al. 2016; Cothran and Van Dyk 1998), but the last representatives of this breed are likely the ancestors of the current Vlaamperd, whose breed association was established in 1983 (http://www.theequinest.com/breeds/Calvinia/).

The Calvinia horse is native to the Western Cape (Porter 2020). The fifth edition of the CAB International dictionary (2002) and the South African Department of Agriculture (2006) indicate that it is an extinct breed, as does DAD-IS,

Fig. 11.28 A South African Vlaamperd stallion. (SAVBS 2019)

which classifies it as a local extinct breed of South Africa (Porter 2020; Cothran and Van Dyk 1998). Similarly, the study conducted by Khadka (2010) describes the Calvinia as an extinct local African horse breed (Khadka 2010). An English-language website states in 2019 that the breed would be "incredibly rare," if it still exists (http://www.theequinest.com/breeds/Calvinia/).

Description and morphology: It exhibits the characteristics of a carriage driving horse. The morphology is light (Dehoux et al. 1996). The coat is generally bay or black. The temperament is reputed to be good and docile.

Uses: There is no specified uses of this horse breed in the DAD-IS database (Dehoux et al. 1996). The constituent crosses and subsequent selection of the Vlaamperd suggest that it was used for carriage driving.

11.2.2.2 Introduced (Exotic) Horse Breeds

Arabian Horse

Due to a performance-based definition rather than one based on morphology, the term "Arabian horse" has been confusing, especially in North Africa. All lightweight horses are given the name "Arabian horse," including Barb horses and Oriental horses. The confusion did not entirely disapper with the creation of studbooks specific to the Arabian horse. It was not until its introduction to racing in the 1970s that a formal distinction was established.

The Arabian horse is present in North Africa, in all countries bordering the Mediterranean Sea, as well as in Mauritania, Senegal, Mali to the west, and Sudan to the east. It is also found in the southern regions of South Africa, Lesotho, Namibia, and Botswana. It has a significant presence in other countries, such as Chad. Its production is overseen by the World Arabian Horse Organization (WAHO), an organization established in 1970, responsible for validating studbooks. The primary aims of Arabian horse breeding are the improvement of local breeds, flat racing, and the enhancement of endurance and walking. Horse shows are held in Egypt, Morocco, and various countries in the south. Some shows are reserved exclusively for the Straight Egyptian type. The most recent of these, the Straight Egyptian World Championship Arabian Horse Show, was held on October 16th–17th, 2021, in Milan. Arabian horses are not used for work.

The Arabian horse can be primarily categorized into two types: the *Saglawi* line with a concave profile, long and curved neck, and usually a bay coat; and the *Muniqi* type, elongated with a straight profile, long back and neck, long legs, and angular morphology. Most are bred on mixed farms with only a few head each. Specialized royal or private stud farms exist in Morocco. In Tunisia and Algeria, only national stud farms like El Batar or Chaouchaoua, with a production of approximately thirty head per year, engage in Arabian horse breeding (Fig. 11.29). Egypt is the only country with studs exclusively specialized in Arabian horses. One of these is EzZahraa Stud Farm with a herd of about one hundred mares. It breeds the Egyptian type of Arabian horses and has become the world's largest Arabian horse stud.

The proven presence of the Arabian horse in Africa dates back to the beginning of the fourteenth century when it was introduced into Egypt by an admirer, Sultan Malik al-Nâsir ibn Sayf al-DînQalawûn. In other countries, its introduction did not truly occur until the late nineteenth century. Horses established in Tunisia by the Phoenicians, which were able to breed, could not be assimilated into the pure Arab race due to its nonexistence at the time. Horses introduced to the Maghreb in the eighth to eleventh centuries through Arab conquest were in small numbers and were met with resistance from local populations who were deeply attached to their own lineages. Consequently, these introductions did not lead to any specific breeding efforts. Scholars Aumassip-Kadri and Souidi agree that, in the absence of such breeding, any introduction would have necessarily been diluted by local stock.

In Egypt, the state has been heavily involved in the breeding of Arabian horses since the seventeenth century. The number of horses was significantly increased at the beginning of the nineteenth century by Mehemed Ali, a devoted admirer of

Fig. 11.29 Algerian native Arabian stallion "SAKHI", senior champion stallion of World Arabian Horse Organization (WAHO) 2014 (http://www.waho.org/algeria)

the breed, particularly after receiving a strong tribe herd of horses from the Nedj during the conquest of that region. His grandson, Abbas I Hilmi, further enriched these numbers with the best Bedouin horses from the Arabian Peninsula. Although the farms were disbanded after his death, proportions were acquired by Ali Pasha Sherif and Lady Blunt, the granddaughter of Lord Byron. They formed the foundation of the English Crabbet stud, and were also used to establish a stud at Sheikh-Obeyd near Cairo. Through astute selection over a few generations, Egyptian breeders created and standardized the "Egyptian Arab" type, known for its dry conformation and distinct expressions, particularly in the head. Presently, breeding efforts are concentrated in northern Egypt, where numerous studs are dedicated to this type, including EzZahraa, founded in 1908 by the Royal Agricultural Society under the chairmanship of Kamel Eddine Hussein. Egyptian breeding activities mainly occur in Lower Egypt and the Nile delta, especially its eastern region and around Cairo. A studbook specifically for the Arabian horse was inaugurated in 1969. It is worth noting that Tahaoui's horse population in Egypt is considered sufficiently purebred Arabian, though not officially recognized.

In the Maghreb countries, the introduction of the Arabian horse occurred in the late nineteenth century. Its presence was driven by the French desire to establish a local horse breed and improve the Barb, which they had access to but which was of low quality. This effort is closely linked to the Pompadour stud farm in southwestern France, where Napoleon initiated the breeding of Arabian horses following his expedition to Egypt in 1798–1801. Little data is available for Libya, where an Arab studbook was established in 1959. Parentage verification was carried out in Morocco by LAGEV in 2011 and 500 Arabian horses were registered.

After years of sporadic and unsystematic breeding, organized efforts were eventually implemented. Currently, much of the workforce has been imported from Tunisia and Algeria and is used in flat racing and endurance events. Arabian horse breeding began in Tunisia in 1881, with the importation of the first four mares from the Pompadour mare farm to the Sidi Thabet breeding establishment. Descendants of these mares were used to create various breeds, resulting in a population of approximately 5000 individuals by 2015. Some stallions introduced from the East and the South-West of France have given rise to the notions of "eastern" and "western" types, with the latter being larger and displaying superior racing performance. These types were separated in 1950 by a beylical decree that established a state monopoly on their importa-

tion. Subsequently, national stud farms initiated substantial breeding reforms.

Under the guidance of Dr. Hosny Khaled, a stringent control system was established for mating and births, requiring them to occur within the enclosures of various national stud farm establishments. In order to prevent inbreeding, Egyptian type Arabian horses were imported in 1970 and 1980, despite their initially modest performance, resulting in the development of a model with international courier qualities.

Under pressure from breeders, several French stallions were imported in 1999, which has led to a dilution of the Tunisian breed's distinctiveness. The El Batar stud now has the responsibility of preserving the breed, managed by the FNARC, established in 1988 as a successor to the original national stud farms founded in 1913. The breeding activities of Arabian horses are primarily concentrated in the northern regions, including Tunis, Sidi Bouzid, Kairouan, and Sfax, as well as the South. A dedicated Arabian horse studbook has been in place since 1956. Arabian horse products are used in crossbreeding with the Barb, as well as in flat and endurance races.

The Arabian horse in Algeria was mainly used as a saddle horse. The first introductions date back to the mid-nineteenth century. During this period, horses from Pompadour and Syria were brough in and primarily bred in the mare farm of Tiaret. This effort led to the creation of a lineage known as Tiaret- line Asil, which held the unique distinction of not having a male line for around 70 years, and it produced horses of remarkable quality. To prevent inbreeding, stallions were imported from Europe (Sweden and England) in 1978. However, by 1990, importation was opened to the private sector, resulting in a disorderly proliferation of parentage, which posed a threat to the unique characteristics of the lineage. In Algeria, Arabian horses are predominantly used in flat races, managed by the Horse Racing and Pari-Mutuel Society (SCHPM), and in endurance races overseen by the Equestrian Federation (FE). They also participate in various competitions, including the Tiaret Horse Show, and engage in traditional activities. The current population is estimated to be around 1000 individuals. Breeding primarily takes place in the Tiaret and Sétif regions. An Algerian studbook specific to the Arabian horse, established in 1932, was adopted in 1982 and is managed by ONDEEC. This organization issues certificate of approval and authorization for breeding stallions, registers each birth, and provides descriptive booklets and registration cards.

In Morocco, the introduction of the Arabian horse took place at the beginning of the twentieth century, leading to the establishment of the Temara and Meknes mare farms in 1906. An Arab stud-book was created in 1982. During the 1980s and 1990s, several stud farms were established. Morocco now boasts 150 traditional Arabian Thoroughbred farms, albeit with a small number of horses. Since 1985, the creation of the Royal Moroccan Association of Thoroughbred Horse Breeders (ARMECPSA) by Hassan II has promoted the breed by allowing crossings only with the most renowned strains.In Mauritania, the Arabian horse is known as a local variant, the Hodh, primarily used as a saddle horse. In Mali, it exists in the Adrar des Iforas region in a local variant. In Senegal, private breeders introduced the Arabian horse around 1950 to enhance local breeds. Additionally, the "*Centre de Recherches Zootechniques de Dahra*" contributed to its introduction from 1959 to 1968. While these populations are heavily influenced by the Arabian horse, they are not officially recognized by WAHO or any studbook.

In Sudan, the introduction of the Arabian horse took place in the twentieth century, driven by a desire to improve local breeds. It played a role in the creation of the Tawleed breed, which has become a local racehorse.In the Southern African countries, the Arabian horse was not introduced until 1902, and its breeding only gained momentum since 1945. This development began with the importation of stallions from England, the USA, and Egypt. A breed introduced in the seventeenth century disappeared due to crossbreeding with Barb, Thoroughbreds, and Persians, resulting in the Cape Horse, which faced disappearance in harsh climates and evolved into the Basuto pony. Breeding of the Arabian horse in these countries is exclusively

private, serving purposes such as racing and crossbreeding with Thoroughbreds and Boerperds.

Thoroughbred Horse

The fascination with horses also reached England, where kings, starting from the sixteenth century, began selecting high-speed horses for racing. To achieve this, they crossbred their local horses with other breeds such as the Barb or the Spanish. After two centuries of experimenting with the local stables, British breeders turned to the horses that English travelers had encountered during their journeys to the East in the late seventeenth and early eighteenth centuries, namely, Arabian horses—known for their speed and robustness. Three stallions gave rise to the entire breeding stock of the future Thoroughbred horses: the Byerley Turk, which originated the lineage of the legendary Eclipse; the Darley Arabian, who fathered the first great racehorse, Flying Childers; and the Godolphin Arabian, ancestor of the famous Matchem and Eclipse.

Exclusively reserved for flat races, Thoroughbreds preceded Arabian horses in African countries. In the countries of Southern Africa, they were imported in large numbers at the end of the eighteenth century and the beginning of the nineteenth century, following the establishment of races. South Africa is the second-largest breeding country in the world, boasting approximately 300 registered active breeders. Around the turn of the millennium, South African Thoroughbred horses managed to win championship races in Dubai, Hong Kong, the USA, Singapore, Australia, and Bahrain, as well as top races in Britain and France. South African breeders have long sought international bloodlines to enhance the local breed.

The Thoroughbred is bred in northern Libya at Al Shaab Stud, the largest Thoroughbred stud in the country. In Algeria, the Laghouat region produces the finest specimens. In Tunisia, breeding is concentrated in the northern part of the country, specifically in the governorates of Ariana, Manouba, and Bizerte. The English Thoroughbred made its appearance in stud farms in Morocco from 1968, specifically in El Jadida. By 1973, there were 160 thoroughbreds racing, out of which 90 were born and bred in Morocco. In these countries, the Anglo-Arab (Fig. 10.12), or more generally, the Anglo-Arab-Barb obtained by crossing the English Thoroughbred with the Arab or Arab-Barb, made it possible to obtain a faster horse than the Arab-Barb. Races serve as its main outlet.

SelleFrançais

The SelleFrançais stands as one of the world's most esteemed breeds of horses for show jumping. The SelleFrançais Studbook secured second place in the 2020 World Breeding Federation for Sport Horses (WBFSH) ranking for show jumping and eventing. A blend of various sport horse breeds, including the Anglo-Normand, TrotteurFrançais, Thoroughbred, and Anglo-Arab, contributes to the SelleFrançais' makeup (Fig. 11.30). It achieved official breed status in 1958.

The Selle Français Studbook orchestrated several endeavors that bolstered breeding abroad. For example, organizing an international SelleFrançais championship in Algeria marked a significant show jumping event on the African continent. Since 2011, the Selle Français has been bred by the Hocine El Mansour stud farm in Mostaganem in western Algeria. It boasts a SelleFrançais breeding core comprising broodmares and performers from SF confirmed in France, notably from the Forêts de Fabrice in Paris. After assessing initial generations, Jean Louis Lenoury, President of SF Judges, affirmed that all signs indicate this breed's excellent adaptation to the country's climatic conditions.

The Moroccan Saddle, designed for equestrian sport and particularly show jumping, stands at a withers height of 1.40–1.72 m. It was developed through crosses between the Hanoverian local breed, for size. The Selle Français for mass, and the Thoroughbred for energy. Presently, this studbook remains open and engaged in the selection process, particularly in Sidi Berni, embracing substantial crosses. Roughly 100 births take place annually across three principal farms situated in Rabat and Agadir, Morocco. As an off-

Fig. 11.30 Anglo-Arab horse. (Image credit: Personal image)

shoot of the French studbook, Morocco plays a vital role in approving the breed's studbook.

An 8-year-old steed, "Mister d'Eclipse," procured as a foal by Jean-Charles Grand Montagne and held in high regard by him, has recently come under the Moroccan saddle. The horse is intended for OuaddarAbdelkebir, a talented Moroccan athlete who qualified for the Tokyo Olympics with "Mister d'Eclipse" and was triumphant in the foreign horse final at Fontainebleau at the age of 6. Notably, the SelleFrançaisImperialed'Euskadi, born in Bidart under the care of Marc Hiriart, found its place with Mohammed VI and is set to join the Moroccan national riding team soon (Fourcade 2021).

Trotteur Français

Initially, the TrotteurFrançais breed emerged from a crossing between the Anglo-Normand and other trotting breeds. This breed primarily engages in sulky races but also in mounted trotting races and various other equestrian disciplines. The TrotteurFrançais was meticulously cultivated for harness racing in nineteenth-century in Normandy. Its foundation stock comprised predominantly of Anglo-Normand, Standard bred, Norfolk Trotter, Thoroughbred, and Hackney horses. Despite the Standard bred's lateral gait, the French Trotter retained its distinctive diagonal trot. Officially recognized in 1922, the breed maintained an open studbook until 1937. TrotteurFrançais horses typically exhibit a longer maturation period but often enjoy extended racing careers (Szathmary 2021).

Algeria and South Africa stand as collaborative partners of the *Société d'Encouragement à l'Elevage du Cheval Français* (SECF), widely known as the *Société du Cheval Français*. In Algeria, 38 annual French trotting horse races take place. There is a dedicated hippodrome and a total of 78 training horses owned by 30 different proprietors. The status of the breed in South Africa remains undisclosed. Morocco introduced the half-blood trotter during its protectorate in 1974, yet only about thirty half-blood trotting horses participated in races, predominantly owned by European breeders across the 75 horse farms. The trotter failed to captivate the attention of Moroccan breeders or studs and gradually faded from Morocco's equestrian landscape (Barakat 1974).

Percheron

The Percheron horse breed emerged in the aftermath of confrontations with the Muslim army between Tours and Poitiers in central France. Historical accounts suggest that the creation of the Percheron involved the integration of horses from the Arabian Desert among those used by the French. These Arabian horses were captured following the successful repulsion of the invasion by Muslims and other eastern nations. In subsequent breeding efforts, another Arab influence likely played a role. Notably, two Arabian stallions, Le Pin Godolphin and Gallipoly, were reportedly utilized to aid the breed's recovery. The Arabian horse's pivotal role in shaping the Percheron's development is noteworthy.

Percheron horses arrived in South Africa shortly before the Anglo-Boer War, and were used in the vineyards and wheat farms of the Western Cape. Their robustness and manageability led to their use in urban areas for heavy hauling tasks, surpassing the strength of oxen. The initial entries into the South African Studbook consisted of two French-imported stallions named Hammer and Jones. Subsequent imports, often orchestrated by the government, continued the breed's expansion, with breeding taking place in state-owned farms and educational institutions such as Potchefstroom, Grootfontein, and Elsenburg near Stellenbosch. A noteworthy endeavor included the crossbreeding of Percheron horses with Spanish donkey stallions at the Onderstepoort Veterinary Institute, where they were employed for pulling ploughing, planting, and harvesting alfalfa until approximately 1970.

In contemporary times, a multitude of private breeders have emerged, elevating the breed's status. The Percheron breed now enjoys recognition at equestrian events such as the Horse Show and other major exhibitions across Southern African countries (Mac 2015).

Quarter Horse

The Quarter Horse, originally known as the American Quarter Running Horse, descended from the first Spanish horses, with Arab blood, and then an English strain. It is a horse with an explosive character in middle-distance races, and is also known for its gentle and calm temperament as well as its versatility. The South African Quarter Horse Association (SAQHA) was started in the 1970s with the importation of American Quarter Horses by Gary Player. More anecdotally, quarter horses were imported as part of a western riding project.

Friesian Horse

The Friesian Horse breed originates from Friesland in the Netherlands (Douma 1994). The inception of the Friesian breed's lineage can be traced back to the first herd book for Friesians, namely "Het Friesch Paarden Stamboek" (FPS), which was established in 1879 in Roordahuizum, Friesland with the aim of improving the breed through pedigree recording and the implementation of stud registers (Douma 1994). During 1906, two Friesian stallions were imported to South Africa, followed by several imports of mares and stallions from the Netherlands. In 1980, the Friesian Horse Breeders' Society of South Africa was established, consisting of 12 members (Campher et al. 1998) and an additional breeders' organization was formed in 1989, namely, the Friesian Horse Studbook of Southern Africa (FPSSA).

Friesian horses became popular in South Africa for recreation but were also used in crossbreeding programs with Hackneys, Boerperds, and other breeds in an effort to improve draught horses (Campher et al. 1998). In South Africa, Friesian horses are currently selected mostly on the grounds of their aesthetic value rather than for functional efficiency. Breeders make substantial financial investments, and therefore, there is sufficient reason to evaluate the genetic potential as well as traits for inclusion in selection programs.

11.2.2.3 Other Variants

There are many other variants with over forty other names, some of which may encompass the same population; the distinctions lie primarily in the breeding grounds and the languages spoken by the breeders. Currently, there are no clues regarding their origins, except for the Somali, an esteemed pony believed to have descended from

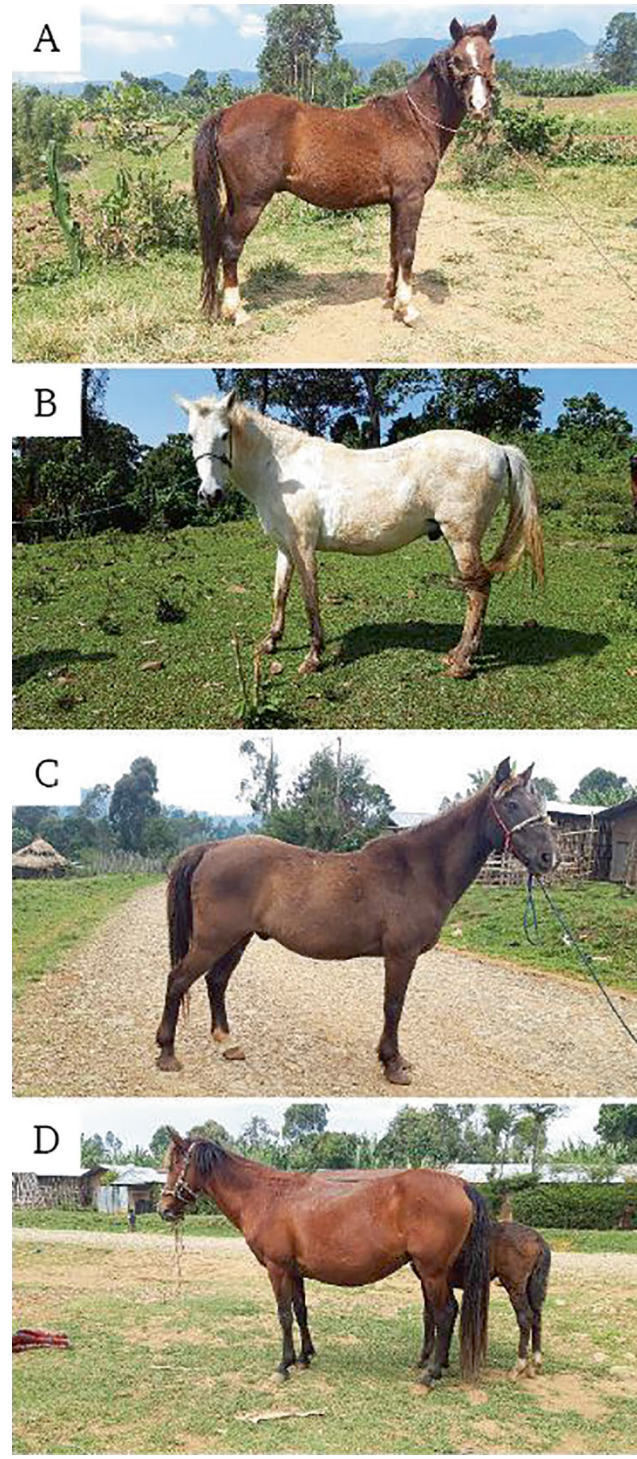

Fig. 11.31 Horse populations from southwestern Ethiopia (Mustefa et al. 2022). (**a**) Telo stallion; (**b**) Masha stallion; (**c**) Gesha stallion; (**d**) Gesha mare (Mustefa et al. 2022)

the Arabs. However, for others like the Berma or Materi found in West Africa (Fig. 11.31), there is little information about their origins. The same lack of origin knowledge applies to breeds such as Gala, Baladi, Egyptian Horse, Dombi, Djerma and Songhoï from Mali, Musey from Cameroon

and Chad, Sulebawa from Nigeria and Minianka pony from Burkina Faso.

In addition, there are a few new breeds or foreign breeds of unknown official descent. The Percheron was found in Burkina Faso. The Breton, a sturdy draft horse, found its way into North Africa, particularly Algeria, to aid in plowing and heavy hauling tasks. They were introduced in significant numbers in the nineteenth century and appear to have no official descendants. In Morocco, they were also used for crossbreeding with the Barb or Arab-Barb, a medium-weight horse not well-suited for strenuous labor. By 1974, only the *Haras de Meknes* in Morocco and a few private individuals continued to maintain draft stallions. Their primary focus was on producing females, which served as the foundation for mule breeding.

Morocco created the Moroccan Saddle with the opening of a studbook in 1985. It is a sport horse, directed toward jumping. It is the product of an initial cross between local Arab-Barb with Anglo-mares. Arab and Anglo-Arab-Barb and Hanoverian stallions, the mares from this first cross were recrossed with Thoroughbred and French saddle stallions and then selected on test. South Africa has recently created two breeds of sport horses. These are the South African Saddle Horse (SAS) and the South African Warm Blood (SAWB). A pet horse called the South African Miniature was derived from a cross between the Shetland and small Arab horses.

Among the African horse populations, there are some that have developed a tolerance to trypanosomiasis, such as the Koto-koli in West Africa, Minianka (Bobo) in Burkina Faso, Koniankan and Minianka in Mali, Musey in Cameroon and Chad, and Logone in Chad and Somalia. These populations are small in size, which raises the question of a relationship with the parasite. The small sizes of these populations are probably linked to their challenging environments.

These remarks make it possible to hypothesize that the West African ponies originate from a reduction or maintenance of the size of the first horses introduced into these regions. They probably measured from 1.10 to 1.30 m at the withers. They came from a slide of the horse from north to south from the second millennium BC, when a domestic horse of the Barb type occupied the central Sahara. In the light of history, it appears that the equine population of Africa rests on a background of Barb and Dongola horses (while waiting to get to know the latter better). Everything suggests that there are different names for the same horse breed arising because they are raised in different regions, or because they belong to "tribes" with different expressions. It is also possible that their isolation in different ecological niches for quite a long time led them to evolve specific characteristics. Behind these names probably exists a wide variety of adaptations that can only be confirmed using molecular approaches.

Over time, stud farms shifted away from mule production to the Barb and Arab-Barb horses, which were better adapted to the natural conditions of the country. The use of French draft horses faced challenges in acclimatizing to local conditions in Algeria. At present, draft horses are no longer present in Morocco (Husser 2017). In Algeria, rare Breton specimens can be found in the western regions of the country. The Arab-Barb horses from Tchad are slightly smaller than the North African Arab-Barb: mares are 1.42 m at the withers on average, while the stallions are 1.47 m. Other horse breeds, including the Anglo-Hispano-Arab, are bred and employed by the military. Argentinian horses, known for their prowess in the sport of polo (Polo Argentino), are also utilized for polo games (Husser 2017).

11.2.3 Horse Production Systems in Africa

Breeding stands as the cornerstone for both the quantitative and qualitative advancement of African equine herds. Its diversity mirrors the horses' utilization and hinges on available natural and human resources dedicated to animal management. The breeding landscape is characterized by the coexistence of a modern system alongside a dominant traditional system. Within

rural farming contexts, almost all horses are reared through the traditional system. In these regions, the equine population's size is closely linked to the agricultural land area cultivated by the farmer. Predominantly, local breeds are the most utilized. Conversely, modern production system finds their foothold in urban and peri-urban areas, where a fusion of local and exotic breeds is kept. Notably, exotic breeds are most generally kept in stud farms. Numerous African nations are grappling with burgeoning demographic growth and the encroaching desertification witnessed in recent years. Consequently, this context has intensified challenges, including disputes over cropland and grazing territories. Thus, there is an increasing recognition of the need to transition gradually from traditional nomadic farming practices toward sedentary or modern farming approaches.

11.2.3.1 Traditional Production System

The horse holds a special place within the African family, being considered an integral part of the family unit. Unlike the donkey, which may receive less care, the horse is often granted preferential treatment. It is not merely a luxury animal but rather a creature of importance. To prevent conflicts between stallions, they are often housed individually in stables composed of a wooden rod palisade topped with a straw roof, allowing proper ventilation (Ndiaye 1978). Traditional stables typically feature a fine sand floor that is frequently replaced. Alternatively, stallions may be tethered to trees, utilizing branches for shade during the day. In such cases, the ground is sandy and regularly cleaned, although non-renewable.

Mares in the traditional system roam freely during the dry season and graze in pastures when it rains and are tethered to stakes or trees in the evenings. They are provided with water and feed, commonly consisting of straw and agricultural crop residues. Stallions are introduced to the pasture only at the start of the breeding season. The primary feed for horses in this system is of plant origin, including fodder, grains, crop residues, and by-products from the food industry. Concentrated feed is rarely employed in this system. Mares are introduced to stallions for mating only during estrus. Foals are usually born at the beginning of the mating season or in the middle of winter (spring in North Africa) (Bazarusanga 1995). During the free grazing period, horses maintain good condition, but they tend to lose weight in the dry season due to a decline in natural pasture quality (Djimadoum 1994).

Traditional herding revolves around free grazing, encompassing two main forms: nomadic and sedentary herding. In nomadic herding, horses, sometimes alongside other livestock, are moved seasonally across expansive regions to locate natural pasture. Sedentary herding, on the other hand, involves raising a smaller number of horses within limited forage areas like fallow lands or village fields. This approach allows for more intensive land use, facilitates livestock management, and enhances product utilization, given the proximity of the livestock to villages. In the traditional rural setting, few animals are housed. Typically, animals are tethered near trees, utilizing the foliage as makeshift roofing. In some cases, they are tethered to open stakes without any cover. Available shelters are basic structures, often constructed with thatched roofs supported by four poles. These shelters provide minimal protection from wind, rain, and dust. The floors are often bare, and bedding is usually absent. Regular cleaning of shelters and makeshift structures is practiced, and the collected droppings are utilized as organic fertilizer in fields, particularly facilitated by ownership of carts (Diouf 1997).

11.2.3.2 Modern Breeding System

The modern breeding system is practiced in urban and peri-urban areas, where horses are accommodated in contemporary stables. This system predominantly involves improved breeds of horses, demanding heightened attention from breeders. Accommodation design often hinges on the specific horse breeds being raised. Modern stables, constructed entirely of concrete walls on suitable grounds, offer optimal ventilation and adequate shade for the horses' well-being (Amiot

1982). Strategic orientation of openings minimizes exposure to winds (Marcenac 1969). These stables might feature automatic feeders and drinkers to enhance efficiency and prevent moisture in the bedding. Straw can be employed to safeguard against bed sores, with stable upkeep undertaken by grooms. Within this breeding system, two types of stables exist: common stables and individual stables. Common stables, situated in single or multiple buildings, may have horses placed in a single row facing the wall and opposite the box entrance, or in two rows placed rump to rump. In stables common to multiple buildings, stalls are replaced by interconnected boxes with contiguous bays. Individual stables, also referred to as breeding stables or boxes, are frequently used for sport horses to ensure improved rest (Ndiaye 1978; Marcenac 1969; Ménard et al. 2002).

Irrespective of stable type or horse breed, high-quality nutrition is essential to meet maintenance and workload demands. While extensive research has been conducted in the field, limited attention has been directed toward the feeding and rationing of African horse breeds in various contexts. This has led to certain differences among breeders concerning feeding practices. This modern breeding method is applied within stud farms and private farms. Stud farms serve as hubs to optimize logistics, pool resources and personnel, and enhance service quality. They facilitate the availability of breeding stations, providing support and services to breeders. Private horse farms range in size, spanning from family-owned farms to large-scale operations. Common challenges in horse breeding, regardless of the operational system, include issues such as animal theft and diseases arising from inadequate breeding conditions (infections, deficiencies, allergies, etc.). Additionally, challenging environmental conditions characterized by high temperatures, humidity, and drought pose significant difficulties. Low socioeconomic status among breeders and limited technical expertise further hinder the progress of equine breeding in Africa. The transmission of contagious and transboundary diseases also remains a significant concern.

11.2.3.3 Horse Production on Multispecies Farms

Horses have shown an ability to adapt when raised with other animal species. Multispecies grazing is a practice observed across various parts of Africa, where horses coexist with different species (camel, sheep, and goat) in a herd (Gherissi and Gaouar 2022; Chergui et al. 2023). The primary consideration here is maintaining uniform pastures. However, there are challenges in managing and optimizing this system, largely because of insufficient comprehension of grazing principles and animal behavior. Multispecies grazing can take two forms: the preservation of animal diversity on pastures either over time or space. For instance, horses may share grazing grounds with goats or cattle, or even partake in a rotational grazing scheme with other species. This necessitates understanding the daily forage requirements of each species, the projected pasture forage yield, and the variations in forage preferences among the different co-sharing species. A comprehensive scientific understanding of animal diversity within African multi-species farms employing horses for various functions is deficient (Dumont et al. 2020; Martin et al. 2020).

Proper horse husbandry demands a minimum daily ration of 50 kg of fodder, potentially supplemented by barley or oats at a ratio of 0.5 kg of grain per 1 kg of fodder. It is imperative to note that exceeding a substitution rate of 60% could lead to colic due to the horse's elongated intestine. Additionally, around twenty liters of clean water are required each day. In a pasture setting, horses require an average of one hectare per horse, subdivided into plots to facilitate vegetation rejuvenation. The presence of cattle can enhance this regeneration process as their consumption patterns differ from those of horses, and their waste contributes to soil enrichment.

The scientific community has recognized certain advantages regarding the environmental sustainability of horse-related breeding. Horses play a role in upholding pasture plant diversity (Loucougaray et al. 2004) and controlling invasive species (Ménard et al. 2002; Loucougaray et al. 2004; Loiseau and Martin-Rosset 1988). However, a significant challenge associated with

multispecies grazing lies in the transmission of nematodes between different species (Dumont et al. 2020; Forteau et al. 2020). Due to these factors, it becomes imperative to conduct comprehensive studies across diverse African regions to ascertain optimal strategies for managing horses within breeding farms alongside various animal species. Such strategies will depend notably on the specific resources available in each country.

11.2.3.4 The Feral (Wild) Horses of Africa

One of the most enigmatic creatures on the African continent is the wild horse of the Namib Desert (Fig. 11.32). For over a century, it has held the status of an exotic species, yet its origins remain shrouded in mystery, giving rise to various theories. Some suggest that these horses may have arrived alongside diamond prospectors, while others propose the intriguing notion that a ship bound for Australia became marooned, inadvertently releasing a cohort of Thoroughbreds (Pinguet 2020). However, the most plausible explanation revolves around the idea that the Namib Desert horse descended from South African military horses that interbred with the Shagya Arabian lineage (Marchant 2018).

In stark contrast, the newly discovered Ethiopian Kundido Wild Horses derive their name from the mountainous terrain where they roam freely (Fig. 11.32). Due to the absence of documented records concerning this equine population, their historical background remains veiled in uncertainty. Insights gathered from focused discussions with local elders, accompanied by a collection of anecdotal narratives (Kefena et al. 2012) shed light on the notion that these horses wandered the expanse of Mount Kundido for an undisclosed time span. These elders within the region propose an intriguing connection between the emergence of Kundido horses in their feral state and the historically significant Ethiopian Muslim-Christian conflict spanning from 1528 to 1560. During this epoch, Ahmed Gragn, the leader of the Muslim forces, clashed with AtseLebnaDengel, commanding the Christian army. It is believed that Kundido mountain, endowed with strategic importance, served as a pivotal military outpost, potentially allowing one of the warring chiefs to leverage its vantage point to impede the advancement of their adversary. Presently, scant substantial evidence exists to substantiate these intriguing conjectures (Kefena et al. 2012) (Fig. 11.33).

Fig. 11.32 Kundido feral horses from Ethiopia. (Kefena et al. 2012)

Fig. 11.33 Namibian wild horses. (Pütz and Schlottmann 2020)

Borana horses in Ethiopia constitute another intriguing wild population, primarily concentrated around the town of Megga within the Borana region. These equines graze across the pastures of southern Ethiopia and are commonly utilized by esteemed Borana Oromo breeders, standing as quintessential representatives of Ethiopian lowland horses. Despite the challenges posed by recurrent severe droughts in the area, these horses exhibit a resilient and robust breed that has adeptly acclimatized to the water scarcity and demanding conditions prevalent in southern Ethiopia (Kefena et al. 2012).

Moving eastward to the Somali lowlands of eastern Ethiopia, we encounter the Somali or Wilwal horses. Among local pastoralists, they are also referred to as "Dirdaa'u" or "Wilwal" horses. Another distinct population of horses resides exclusively in the wild within a region called Aware, positioned on the border between Somalia and Ethiopia. Regrettably, a lack of documented origins hinders our understanding of the Wilwal horses' heritage. Local informants speculate that they may have migrated into Ethiopia from the Nugal Valley in Somalia. Wilwal horses stand out for their robust physique, sleek form, and notable elegance, often characterized by their impressive height (Kefena et al. 2012).

While there exist substantial tracts of suitable habitat for *E. ferus* in sub-Saharan Africa, Australia, and New Zealand, the prospects for rewilding this species in these regions are less evident. This is due to the fact that *E. ferus* is not indigenous to any of these areas (Naundrup and Svenning 2015). The presence of ecologically and socio-behaviorally similar species, such as zebras (*E. quagga, E. zebra, and E. grevyi*), likely plays a role in excluding *E. ferus* from sub-Saharan Africa. These zebras' striped skin provides a defense against tsetse flies, potentially minimizing the risk of trypanosomiasis, a disease transmitted by these flies (Caro et al. 2014).

Notably rugged and adaptive, these wild horses have demonstrated a remarkable ability to thrive in challenging terrain and environments that could prove inhospitable for numerous other species. During droughts, they can endure up to 30 h without water in the summer and up to 72 h in the winter. Extensive research has revealed that over the span of a century living in these arid conditions, the Namib Desert horse population has evolved physiological mechanisms that significantly enhance their water conservation capabilities (Marchant 2018; Hall et al. 2018). In the late 1990s, a severe drought led to distressing scenes of emaciated and ailing horses, prompting public outcry and the emergence of private initiatives, notably the Namibia Wild Horses Foundation (NWHF). These efforts exerted pressure on the Ministry of Environment and Tourism,

Fig. 11.34 Feeding of the horses with hay. (Pütz and Schlottmann 2020)

eventually leading to the legalization of hay feeding for horses during drought periods (Pütz and Schlottmann 2020) (Fig. 11.34).

11.3 Structures and Organizations of the Equine Sector in Africa

11.3.1 Regulations and Legal Bases of the Horse Industry

Horse husbandry in Africa boasts a rich historical legacy and tends to flourish within communities that hold horse riding in high esteem. While a handful of countries, Tunisia for instance, have established and closely monitored stud farms, particularly for breeding Arabian horses intended for horse racing, the broader regulatory landscape remains significantly under-documented. Regulations primarily revolve around the procurement and ownership of horses, with less focus on their management. The multifaceted uses of horses are generally ingrained in traditional and religious customs.

Hippophagia, the consumption of horse meat, is strictly regulated and prohibited in African countries where strong Muslim beliefs prevail (Benkheira 2000). Islam and specific Christian sects, along with traditionalist groups, vehemently oppose this practice (Blench 2000). Conversely, due to societal taboos, hippophagia remains inadequately documented and regulated. In Cameroon, certain communities, particularly in urban centers, display an avid interest in horse meat (Nyock 2014), often driven by elitism. The availability of horse meat is occasionally facilitated through cross-border trade. A parallel scenario unfolds in Nigeria, where a thriving horse trade is evident, likely echoed across the West Coast of Africa (RIM 1992). Similarly, in Chad, due to limited legislation in this area, no comprehensive data is available regarding the contribution of equine meat to the butchery trade, despite its existence. This discrepancy can be attributed, in part, to the fact that horse breeding's primary objective is not meat production but rather encompasses agriculture, transportation, traditional rituals, racing, and even battle. The influence of cultural taboos further compounds this lack of documentation, exposing the species to inadequately regulated practices across most countries (Ndiaye 1978).

11.3.2 Official Equestrian Institutions and Authorities

11.3.2.1 Institutional Equestrian Authorities

Stud farms are present across various African countries, contributing to the advancement of horse breeding. In Algeria, the national Chouchaoua Stud is located in Tiaret, alongside the National Center for Artificial Insemination and Genetic Improvement (CNIAAG), both equipped with frozen semen production centers. Morocco hosts five significant studs: Meknès, Oujda, Marrakech, El Jadida, and the Bouznika studs, which features a frozen semen production center under the CNIAEB (Haras Régional de Bouznika, 2006). Tunisia is home to the El Batan and Sidi Thabet national studs. In some instances, mare yards dedicated to breeding and brood mare production are established. The fundamental role of these studs is to promote and enhance the equine sector, boosting horse numbers and elevating their value. A core focus is placed on both quantitative and qualitative development of the equine population. Premium stallion coverings are monetized, and breeding competitions are held to recognize top-performing horses, guiding breeders in qualitative progress. Additionally, studs engage in research to enhance equine behavior, health, and fertility. Genetic, infectious, and hereditary disease studies, as well as advancements in breeding methods like natural reproduction, artificial insemination, and embryo transfer, are supported by the studs.

Collaborative partnerships extend beyond studs, involving organizations and associations in each country. For instance, in Algeria, the National Office for Equine and Camel Breeding Development (ONDEEC) operates under the agricultural ministry. ONDEEC oversees users, breeders, and their associations, contributing to breed preservation, development, promotion, and studbook maintenance. It allocates a portion of the Pari Mutuel Urbain stakes to fund its activities. Morocco features the Royal Society of Encouragement of the Horse (SOREC), facilitating efficient management and acting as a link between horse breeding and racing. SOREC supervises codified horse racing societies and regional horse racing societies, housing the Consultative Committee for Races (CCC) and Pari Mutuel Urbain Marocain (PMUM).

Stallion depots and breeding stations play a pivotal role, concentrating on breeding elite individuals on stud farms and then distributing them to locations across the region for mare coverings. This gradual enhancement of the entire herd according to breed-specific criteria aims to benefit breeders and access stud farm services. These stations can host local breeding competitions, attracting breeders, public interest, and serving as training grounds. Algeria possesses two national breeding depots and a diminishing number of breeding stations, while Morocco boasts 53 breeding stations and an Equine Breeding Promotion Center.

The realm of horse racing involves organizations responsible for overseeing, organizing, and supporting horse races. South Africa features the National Horse Racing Authority and Racing Association, while Algeria operates the Horse Races and Mutual Betting Society (Decree No. 87–17 of January 13, 1987). Morocco's Consultative Committee of Races (CCC) and PMUM, along with Tunisia's Company of Horse Races (SCHT 2012), contribute to this vibrant sector.

Horses are also significant in the military domain, engaging in homeland security, equestrian sports, and parades. Notably, the Royal Armed Forces' equestrian center in Morocco and the Republican Guard's horse breeding center in Algeria underscore the military sector's investment in equines.

11.3.2.2 Socio-professional Organizations and Associations

The Equestrian Federations of African countries are associative organizations that play a crucial role in regulating various sectors, particularly in the realm of sports. Their primary objective is to promote, guide, and coordinate modern equestrian sports activities involving horses or ponies. They hold a vested interest in the development of traditional sports like Fantasia. Furthermore,

these federations aim to foster an appreciation for equestrian activities among young individuals and actively participate in controlling their instruction. Their role extends to the governance and organization of equestrian competitions. Operating autonomously, these federations also fulfill their public service mission within their disciplines, adhering to both country-specific regulations and those established by the International Equestrian Federation (FEI), to which they are affiliated.

The African Equestrian Federation (FEA) was established in Cairo in 2002, prompted by the President of the Egyptian Equestrian Federation. The founding countries include Botswana, Congo, Egypt, Mauritius, Niger, Senegal, Sudan, and Zimbabwe.

The African Confederation of Equestrian Sports (ACES) stands among the five continental associations acknowledged by the FEI, the global governing body for equestrian sport. Presently, twenty African nations possess national organizations recognized by both the FEI and ACES. The Egyptian Equestrian Federation (EEF) holds the distinction of being the oldest member, joining the network in 1946, while the most recent addition is the Angolan Federation of Equestrian Sports (FADE), which joined the network in 2014.

In Morocco, the SOREC (Société Royale d'Encouragement du Cheval) plays a pivotal role by managing the entire equine sector using modern methods, characterized by efficient and transparent management. SOREC serves as the vital link between horse breeding and horse racing. It oversees codified horse racing societies and regional horse racing societies, with two key bodies based at its headquarters: the Consultative Committee of Races (CCC) and the Moroccan Pari Mutuel (PMUM).

Within the professional equine framework, there are various associations, including breed associations, that aim to spur the development of breeds and equestrian activities specific to each region. These associations propose development programs, undertake initiatives to promote particular breeds, and establish sectors devoted to those breeds. For instance, in Morocco, significant associations include the National Association of Barb Horse Breeders (ANECB), the National Association for Equestrian Tourism (ANTE), and the Moroccan Royal Association of Arab Purebred Horse Breeders (ARMECPSA).

In Algeria, the infrastructure for breed promotion units is not yet fully established, and breeders and owners of recognized purebred horses lack well-structured specific associations. The National Association of Breeders and Owners of Purebred Horses (ANEPCRP) is the most well-known to date, with accreditation from the Ministry of the Interior (accreditation 29 of 25 April 1993, Ministry of the Interior). The Adjr Foundation for the Promotion of the Horse is particularly interested in the enhancement of the Barb breed. In Algeria, there are 350 traditional equestrian associations spread across the entire national territory, responsible for promoting the Fantasia tradition. The direct involvement of breeders in these associations is highly encouraging.

In South Africa, the Thoroughbred Breeders Association (TBA) comprises 193 registered Thoroughbred studs, 509 registered breeders, and approximately 13,500 Thoroughbred horses. The South African Jockeys' Association, a national body representing licensed jockeys, is recognized by all key players in the South African racing industry and abroad (Pienaar and Du Toit 2008). The National Horse Racing Authority (NHA) in South Africa acts as the regulatory authority for the Sport of Thoroughbred horse racing. In this country, horse racing is overseen by two organizations: Phumelela Gaming and Leisure Limited and Gold Circle.

Both governmental and non-governmental organizations and associations are involved in the conservation of certain African horse breeds and the development of equestrian activities. These include the World Organization of the Barb Horse, which coordinates national breeders' associations, manages stud books, establishes breed standards, and enforces regulations related to the reproduction of the Barb breed and its derivatives. The headquarters of this organization are located in Algiers. Presently, it has eight member countries, namely Algeria, Morocco,

Tunisia, France, Germany, Belgium, Switzerland, and Luxembourg (OMCB 2012).

The World Horse Welfare Organization (WHWO) operates predominantly in South Africa, collaborating with the Cart Horse Protection Association in Cape Flat. It is in the process of establishing a network of horse welfare organizations across the Western Cape. The organization's mission is to support and enhance the horse-human partnership in all its forms (WHWO 2021). The Society for Animals and Nature Protection in Morocco, affiliated with SPANA of Great Britain, participates in various training courses for veterinarians and farriers, as well as influencing the evolution of equine sector legislation in collaboration with local authorities (SPANA 2008). The American Fondouk in Morocco provides free treatment to working animals and other animals owned by economically disadvantaged individuals. This organization collaborates with American veterinarians, Moroccan technicians, and workers, treating 50–100 animals daily, totaling over 18,000 animals annually (York and Ulrich 2009).

11.3.3 Infrastructure and Support Structures for the Horse Industry in Africa

11.3.3.1 Training Institutions for Horse Tradesmen

Cavalry training institutions are specialized in providing training for technicians in various equestrian trades. Examples of such institutions include the Royal Cavalry School of Témara in Morocco 137, the Equestrian Training Institute in Johannesburg, South Africa, and the Equestre Center d'OuledFayet in Algeria.

11.3.3.2 Research Institutions

On the African continent, there are a total of 77 university training establishments dedicated to veterinary medicine (OIE 2021). These institutions, along with those specialized in natural and life sciences, as well as scientific research establishments, are responsible for educating veterinary doctors and researchers with a focus on equine health and management. These trained professionals are involved in stud farms where they manage animal husbandry, breeding, and equine health. They also engage in scientific research covering various aspects related to the health, conservation, and enhancement of local horse breeds, as well as those intended for sports and cultural activities specific to each region.

Notable examples of these institutions include the National High Veterinary School and the National Institute of Agronomic Research. Their services primarily encompass the identification and verification of origins, genetic characterization of equine populations, prevention of hemolytic disease in newborn foals, detection of genetic and contagious diseases, and gene typing. Research is conducted at horse stud farms in collaboration with a network of partners, including veterinary faculties, universities, and horse breeding organizations. These establishments also undertake additional initiatives to enhance the health, behavior, and fertility of horses.

11.4 Use of the Horse in Africa

11.4.1 Traditional Uses of the Horse

The horse was initially domesticated and subsequently spread by humans who employed it in various activities such as agriculture, hunting, transportation, sport, warfare, and monitoring of other domestic animals. This domestication of horses played a pivotal role in the advancement of trade and the emergence of civilizations across expansive territories. Often referred to as "the noblest conquest of man," the horse holds a distinct position among all animals due to its profound impact on human history and progress. Its contributions extend to sociocultural and economic advancements.

The breeding of horses, including ponies, proves to be a highly lucrative endeavor in specific regions of the Sahel, yielding significant "invisible" income from horse marketing (Blench 2000). This activity not only underscores the economic viability of horse production but also

highlights its broader implications for the local economy and society.

11.4.1.1 Agricultural Work

In sub-Saharan Africa, the majority of farmers operate mixed production systems on small plots of land, usually smaller than four hectares (Pearson and Vall 1998). For these farmers, animal energy offers an alternative to manual labor for both cultivating food crops (such as cereals in semi-arid zones and tubers and plantains in wetlands) and growing cash crops (like rice, cotton, peanuts, coffee, banana, and cocoa) (Starkey 1994). These animals also have roles in crop-related tasks and water pumping. When equipped appropriately, they rotate wheels to crush grains and power water pumps. In this manner, an individual can pump 3600 liters of water from a depth of 10 m in just 20 min (Oudman 2004). Animals are employed as draft animals to pull heavy loads and even for plowing (Cynthia 2011). The animals used in these settings are characterized by their dense bone structure and robust legs. Draft horses, in particular, are known for their sturdy build, pulling strength, and docile nature. Generally weighing between 700 and 1000 kg, they stand at a height of approximately 160–180 cm at the withers.

The advantage of horses and donkeys lies in their overall faster movement compared to work oxen. As a result, equines are selected for tasks that require lower traction forces, such as transport, sowing, and weeding on light sandy soils. For instance, in West African countries like Senegal, Mali, and Niger, direct sowing of crops like groundnuts, millet, and sorghum is widely practiced using a single donkey or a small horse. This approach allows swift seeding over large areas to enhance crop success, particularly in light sandy soils of semi-arid regions with uncertain rainfall (Pearson and Vall 1998). Despite this, animal energy is used in only about 15% of cultivated land in sub-Saharan Africa (Jahnke and Sievers 1981; FAO 1987). In Senegal, for instance, where mechanization is absent, all agricultural activities rely heavily on animal energy provided by equines (Ly et al. 1998).

Draft horses play a crucial role in both agricultural production and transportation across sub-Saharan Africa 229. According to Ndiaye (1978), an adult horse can cover a daily agricultural area of 3.5 hectares, while a pair of oxen can cover eight hectares (Ndiaye 1978). Similarly, a young horse can manage 2.5 hectares per day, whereas a pair of oxen is limited to three hectares. Furthermore, horse-drawn carts are widely used to transport agricultural inputs (such as fertilizers, pesticides, and seeds) and agricultural products (harvests, animal products), facilitating distribution and marketing.

Analyzing the profitability of a work horse, a horse with dimensions of 1.35 m at the withers and a chest circumference of 1.45 m is estimated to have a power of D = 22.5 C2 based on Dechahbre's formula for European work horses. However, for the horses studied by Ndiaye (1978) in Senegal, a value of D = 20 C2 was adopted, corresponding to D = 42 kg m/s. These horses work for a minimum of 5 h per day (Ndiaye 1978). Nonetheless, work capacity encompasses more than just the animal's power. Tolerance to heat is crucial and directly affects the work output, especially in hot climates where exertion generates additional heat stress. Work potential is a combination of pulling power, speed, and endurance. Some of these traits can be genetically enhanced (Rouvier and Wiener 2009). Equines generally work faster than cattle. When the labor force increases, both speed and work duration tend to decrease. Finally, heavier horses exhibit greater endurance during intense pulling tasks. Horses display rapid recovery and a minimal response to the Temperature Humidity Index (THI). The THI-induced increase was around 1.0–2.0 °C in donkeys, 0.5–1.8 °C in zebus, and 0.5–1.2 °C in horses. Additionally, horses exhibit high energy expenditure compared to maintenance—about 2.24–2.50 times their maintenance level (Perez et al. 1996).

Genetic studies have enabled the estimation of the heritability of traction force: h2 = 0.20, indicating relatively low heritability. The Mbayar horse in Senegal is considered a foundational breed for draft horse production due to its conformation and capabilities. In North Africa, the draft

horse, typically of Arab-Barb breed or unrecognized origin, is utilized for agricultural tasks like plowing, water transportation, and threshing. However, other draft animals like donkeys and mules pose a threat to this horse population, as the growing ratio of mules to horses implies a shift in production toward mules (Bouazzaoui 1998).

In rural areas, the agricultural draft horse and horse-drawn traction continue to play a crucial role in trade, marketing agricultural products, transporting construction materials, and collecting household waste (Starkey 1994; Akpo 2004; Bathily et al. 2014). Notably, the use of horses in agricultural work is prevalent in developing countries, accounting for 25% of plowed areas in Africa (Bathily et al. 2014). In urban settings, a distinction is made between horse carts, mainly used for transporting materials and goods, and cabs, employed for people transportation (Bathily et al. 2014).

Additionally, organic matter resulting from animal excreta (feces and urine) mixed with litter (such as straw and fern) after composting serves as a fertilizer in agriculture (Oudman 2004).

11.4.1.2 Transportation

The utilization of animal traction for transport was initially introduced in African coastal and inland ports between the seventeenth and nineteenth centuries (Starkey 1994). As favorable social, economic, and ecological conditions emerged, this technology gradually spread across the African continent, facilitated by traders, colonizers, missionaries, and administrative authorities (Bathily et al. 2014). Despite the advent of agricultural mechanization and the increasing dominance of draft oxen, the horse continues to serve as a work companion for peasants in certain African countries. It is estimated that working equines support approximately 600 million people worldwide, especially in impoverished and marginalized communities (Valette 2015). In rural Africa, working equines stand as the primary means of transport and traction, upon which rely the production chains of various sectors such as construction, agriculture, and the transportation of people and goods (Figs. 10.15 and 10.16).

Transport horses are employed either as riding mounts or harnessed animals. In Africa, you can find elegant and lightweight horse breeds from the northern regions, as well as robust breeds from the eastern areas. Additionally, there are pony-type equines, which are essentially small horses at adult age (measuring less than 1.49 m at the withers). Ponies typically originate from sub-arid and arid regions where food might be scarce, and temperatures can be extreme (Porter 2020). There are various types of ponies that are easily managed for riding purposes. These include the Logone Pony, Middle Logone Pony, Hoho Pony, Kabbia Pony, M'Par Pony, Cayor Pony, and others. These stocky and robust animals are small (weighing around 200–250 kg), yet resilient and enduring (Nyock 2014).

Horses that are suitable for riding are relatively light and better suited for the purpose compared to those intended for harnessed transport, which require greater robustness. During the twentieth century, horses were somewhat neglected due to the industrialization and mechanization of societies in developed countries and those that followed suit. In recent times, the use of horses for transportation is declining sharply while their use in performing many other tasks is increasing.

In developing African nations, particularly in rural regions with challenging conditions, horses continue to contribute significantly in the transportation of construction materials, goods, and water in places often inaccessible to motor vehicles. They are also employed for people transportationand for the collection of household waste or water in large cities in South Tunisia (Figs. 11.35 and 11.36), Dakar, and Cairo.

11.4.1.3 Production of Mullets and Hinnys

One of the valuable contributions that horses can make in agriculture is the production of hybrid animals that exhibit enhanced robustness and resilience to the challenging conditions of dry areas. The crossbreeding of different equine species, such as horses and donkeys, results in hybrids that possess distinctive characteristics. However, these hybrids are predominantly sterile

Fig. 11.35 Plowing with horses. (Image credit: Author's Own 2022) (Kebede 2023)

Fig. 11.36 (**a**) Barb or Arab-Barb horse-drawn cart for passenger transport; (**b**) Horse-drawn cart with pneumatic wheels and elevated platform used for transporting goods in Tozeur region of Tunisia. (Charles 2022)

due to their chromosomes being precisely intermediate between those of the two parental species (Petrus 2003). Specifically, they contain 64 chromosomes from the horse, 62 from the donkey, and 63 from the mule and hinny (Trujillo et al. 1962). Despite their occasional sterility (Jussiau et al. 2013), mules and hinnys inherit the strength of horses along with the robustness and hardiness of donkeys (Petrus 2003).

Mules exhibit a blend of the morphological traits of their two parent species. They possess a size that falls between that of a donkey and a mare, while their physical characteristics resemble those of a donkey. Hinnys, similarly, resemble mules in appearance but tend to be larger. Hinnys lean toward the horse in terms of conformation and are capable of consistent daily work, contributing to the improvement of living conditions for many individuals in rural areas. On the contrary, quantifying the productivity of the hinnys, being a nonfood agricultural species, is a more complex endeavor. These hybrid equine species represent a fusion of the advantageous traits from their parent species, creating animals that are uniquely suited to particular tasks and environments, such as the demanding conditions of arid regions.

11.4.1.4 Hunting

To provide a sense of the endurance and swiftness of Sahelian saddle horses, it is essential to recall instances from colonial times when references document successful gazelle and antelope hunting on horseback. During these hunting expeditions, hunters managed to capture gazelles and antelopes due to the exceptional stamina of their horses. This echoes historical traditions seen in earlier centuries with breeds like the Arabian horse in the Middle East and the Barb horse in North Africa. Consequently, Sahelian saddle horses stand on an equal footing with renowned historical breeds. It is highly likely that the last deserts where riders on horseback pursued and caught gazelles and antelopes were not in the Middle East or North Africa, but in the Sahel region (Belin de Launay 1877; Gillet 1964). This showcases the impressive capabilities of Sahelian saddle horses, highlighting their endurance and speed in a manner reminiscent of these distinguished historical equine breeds.

11.4.1.5 Cattle Herding

Horses have played a significant role for generations in various parts of Africa in assisting with the herding of other animals, including cattle, sheep, and goats (Oudman 2004; Eulmi et al. 2023). Numerous pastoralist communities have integrated horses into their practices for sedentary, transhumant, or nomadic livestock management. A prominent example is observed among the Fulani people in the Sahel region. In extensive livestock production, the use of horses for controlling and managing cattle herds is most prevalent in South Africa. In this country, the American Quarter Horse is commonly employed as a working cow horse by South African cowboys. These ranchers require a small, agile, and highly nimble horse capable of maneuvering effectively in challenging conditions and displaying assertiveness around livestock, while being safe for a young child to ride. The horsemanship displayed by South African cowboys is held in high regard, and an increasing number of riders seek them out for lessons. Despite the challenges posed by the African climate, these cowboys are driven by a deep love for their horses (AQHA: American Quarter Horse Association, Undated).

11.4.1.6 Family Celebrations

In societies rich with equestrian traditions, the horse holds a central role in expressions of joy and celebration. As such, the horse is perceived as a symbol of reward due to its prestige and status in society. Its presence, particularly when employed as a mount or escort during marriage ceremonies (Figs. 11.37, 11.38, 11.39 and 11.40), holds great cultural significance (Westermarck 2003). In certain communities, the horse even plays a part in the dowry process. For instance, within the Grassfields communities of Cameroon, the use of the ponytail is a widespread practice in funeral rituals and traditional ceremonies, and symbolizes victory among these peoples (Nyock 2014) (Fig. 11.41).

However, customs surrounding horses vary widely, not only from one country to another but

Fig. 11.37 Weeding festivity in Chechar city, Khenchla (Algeria)

Fig. 11.38 Rider and horse (caparisoned for a wedding ceremony) performing the pace walk. (Baynes-Rock and Teressa 2021)

Fig. 11.39 Awi Agew horse riders during an annual festival. (Kebede 2023)

also between tribes and even within the same tribe (Figs. 11.37, 11.38, 11.39 and 11.40). In specific regions of northern Africa, the father of a young girl might desire one or more mares as part of what he seeks from the family of the man proposing marriage to his daughter. Likewise, the groom's family might offer horses to the bride's family. In some instances, the bride could return to her new home on horseback, especially if the distance to be covered is considerable. The horse chosen for this purpose could be either a mare or a stallion. They believe that using a mare would ensure the bride's fertility, while employing a stallion would increase the likelihood of her bearing male children. In either case, the animal the bride rides is often believed to have a magical influence on her (https://www.aucoeurdeschevaux.com/f/foutanke-131/). It is important to note that customs are far from uniform, varying not just between countries and tribes but also within the same tribe. These practices underscore the diverse ways in which horses are woven into the fabric of cultural celebrations, rites, and rituals, reflect-

Fig. 11.40 Fulani horses performing a traditional dance at the conclusion of Ramadan. (Image credit: Flickr/ Rosemary Lodge) (DLIFLC 2018)

Fig. 11.41 Ndop loincloth during funerals, Cameroun. (Image credit: Foréké Dschang 2017) (Noel 2021)

ing their profound significance across different societies.

In any case, the saddled horse should not be taken without a rider. For the journey, a brother, a cousin of the groom, or a young boy could ride the mare. An empty saddle is considered a bad omen. When moving the procession to the bride's family house, the mare is sometimes led by hand. The groom's sister or sisters could grasp the tail, while two other people walk on each side with their hands on the stirrups. Upon the convoy's arrival at the bride's village, it might be pelted with stones, mimicking an enemy troop, before receiving a cheerful welcome. This reception likely symbolizes resistance to the young girl's departure (https://www.aucoeurdeschevaux.com/f/foutanke-131/).

The circumcision ceremony in certain communities sees the youth treated like a newlywed. Just like a groom, he is paraded with grandeur and accompanied by music prior to the ceremony, passing through the main marabouts of the city (El-Alami 1971). Traditionally, this parade takes place on horseback, symbolizing virility, power, and pride. However, due to the decline in horse population, rural migration, and mechanization, this tradition has become less frequent, but it remains more prevalent among the working classes. Fantasias are occasionally organized during these events.

11.4.1.7 Pilgrimage to Mecca

The horse is regarded as a prestigious animal, affording its owner a position of honor in societies with an equestrian tradition. As a means of upholding specific traditions, particularly in the Maghreb region, it is not unthinkable that even making the pilgrimage to Mecca on horseback is deemed a noble endeavor.

11.4.1.8 Parades

The horse has maintained a connection with authority since ancient times. Despite the advancement of transportation industries, the horse remains linked to activities involving demonstrations or displays of prestige and power. In the United Kingdom, as well as in most Western countries and parts of Africa, ceremonial cavalry units exist (Figs. 11.42, 11.43 and 11.44). Some public appearances occur exclusively during national holidays in the political capital.

The horse is a prominent presence in parades on numerous occasions, including religious festivals, national celebrations, sporting events, and cultural festivities. In South Africa, the Durban July gathering, a horse event that has attracted horse enthusiasts and luxury aficionados for over 120 years, takes place annually (Fig. 11.45). This event includes a horse parade and races, with wagers surpassing US$30 million in 2016. In the North Cameroon region, select religious leaders use prestigious horses, particularly as symbols of authority, especially those with white markings on all four legs.

In Northern Nigeria, an area steeped in the history of ancient Islamic kingdoms, the annual Durbar Festival is celebrated in states such as Kano, Katsina, Zaria, and Sokoto. Initially associated with wartime allegiance, the festival features a display of horsemanship in front of the Emir to demonstrate the readiness and loyalty of his regiments. The Durbar showcases vibrantly attired horsemen in colorful traditional attire and turbans, led by local leaders, musicians, and traditional performers. These horsemen proceed by regiments to the Emir's palace, punctuated by the sound of muskets, delighting the palace audience as they pay homage to the Emir. This vibrant event, known for marking significant Islamic holidays like Eid-al-Fitr and Eid-al-Adha, is a testament to the region's rich cultural heritage (Okoro 2017). In April 2021, a grand historical procession took place involving the transfer of 22 mummies from the Egyptian Museum in Tahrir to the National Museum of Egyptian Civilization. This skillfully orchestrated show included 150 horses adorned in Pharaonic attire, pulling chariots accompanied by extras in period costumes. Drums and symphonic music provided a dramatic backdrop to the spectacle.

Across various African nations, festivals dedicated to horses are regularly organized. Examples include the national horse festival in Tiaret, Algeria; the horse show in Jadida, Morocco; the horse festival in Parakou, Benin; and the West African Horse Show (SOAC).

Fig. 11.42 Fantasia in Northern Cameroon. (Image credit: Félix Meutchieye)

Fig. 11.43 Horse show at Jida horse market in Ethiopia. (Kefena et al. 2012)

These events serve as opportunities for riders to participate in parades, while folklore troupes follow suit in a jubilant atmosphere characterized by vibrant colors and cultural and traditional inspirations. Similar occasions occur in other African regions, such as Gaani in Nikki (northeastern Benin, near the Nigerian border). In Burkina Faso, the Peuls of the Barani department, situated close to the Malian border, continue the tradition of organizing equestrian gatherings during the Tabaski (Aïd-el-Kebir) holiday. These gatherings often involve parades of lavishly adorned horses, accompanied by riders in traditional garb, constituting opening and closing ceremonies (Adapted from the original text).

11.4.2 Equestrian Sports

Horse shows are hosted in most countries as platforms to promote the discipline. Governed by regulations established by Equestrian Federations, these shows encompass a range of disciplines including dressage, show jumping, endurance competitions, and the complete equestrian competition (CEC), which combines dressage, cross-country (merging jumping and endurance), and jumping obstacles. Equestrian sports find expression through equestrian centers, each accompanied by a multitude of equestrian clubs and farms. The concentration of equestrian centers is notable along the Atlantic and Mediterranean coastlines. Countries such as Algeria, Morocco, Nigeria, South Africa, and Tunisia boast more than fifteen centers affiliated with their respective Equestrian Federations. Despite the development and organization of equine sports activities in other continents, the same progress is yet to be fully achieved in Africa. This is primarily due to the relative sketchiness of regulations in the region, even though the significance of the sport and its associated opportunities is not to be underestimated.

11.4.2.1 Horse Racing

Horse racing stands out as the most prevalent sporting activity on the African continent,

although its development remains limited, except in South Africa. Only a handful of African countries lack a hippodrome, with many also hosting informal races on unfenced grounds. Senegal boasts three enclosed hippodromes and sixteen municipal ones. Algeria and South Africa both feature eight equipped hippodromes, while Morocco has seven. These venues cater for flat races, spanning distances from 1000 to 2400 m, and are guided by racing codes. Saddle horses and those intended for equestrian sports typically exhibit warm-blooded characteristics. Morphologically, they are often slender at the extremities, with a withers height ranging from 140 cm to 175 cm and a live weight between 380 kg and 600 kg (Cynthia 2011).

The Thoroughbred, Arabian horse, Dongola, and, to a lesser extent, the Arab-Barb horse, are prominent choices for flat racing. Various other horse breeds are esteemed in different African countries, such as Arewa and Foutanké in West Africa, Koto-Koli in Nigeria and neighboring nations, and Gondo in Mali. The Sudan Country-breed, a result of crossing local horses with English and Arabian Thoroughbreds, and the Tawleed, obtained by crossing local horses with English Thoroughbreds, are highly regarded for racing. Morocco also engages in Anglo-Arab races, while Algeria hosts trotting races featuring Half-bloods. In several countries, horse racing, in part or whole, supports the equine sector through entities like the Pari Mutuel Urbain (PMU). Given its popularity, the racing sector significantly contributes to herd development and enhancement, largely due to its role as a promoter of peace, moral support, and social cohesion. Periodic competitions occur between local and cross-border teams, as seen in the cases of Cameroon, Nigeria, Niger, and Chad. In Cameroon's Adamawa region, horse breeding primarily centers around racing, supported by horse racing associations like CACGALLOP (The Horse Friends Club) and CAMGALLOP (Cameroon Horse Racing Cup) (Nyock 2014; Mohamadou 2007). The finest Thoroughbreds utilized in European horse racing often hail from Tunisia.

In South Africa, horse racing enjoys immense popularity among the affluent and well-known individuals of the country. Starting from humble beginnings in the late 1700s, horse racing has grown into a multi-million-rand pastime, engaging thousands of participants and garnering widespread support. Within South Africa, three renowned horse races occur in its principal cities. Johannesburg hosts The Summer Cup, boasting a first prize of R1.2 million in prize money. Cape Town is the venue for The J&B Met, held at Kenilworth Race Course, while Durban hosts the prestigious event known as The Durban July, a tradition that dates back to 1897. South Africa also has a number of world-class venues for hosting horse races. In the Eastern Cape, there are the Arlington and Fairview racecourses. The Free State is home to the Bloemfontein and Vaal racecourses, and Gauteng is recognized for its Newmarket and Turffontein racecourses.

11.4.2.2 Endurance Raids

Endurance raids are a practiced discipline that occurs outside of equestrian centers. They involve covering long distances (ranging from 10 to 160 km) over the course of one or more days along a marked route, with the option of following either an imposed or free speed. The well-being and health of the horse are taken into consideration through veterinary checkpoints placed along the route. TREC encompasses multiple equestrian practices, including orientation and regularity courses (ORC), courses across various terrains (PTV), and pace control and presentation activities that focus on harness utilization.

Endurance riding, characterized by its extreme distances and breathtaking landscapes, is both intense and tactical. The sport places substantial demands on mental and physical strength, offering a test not only of the body but also of the mind, with the well-being of both the athlete and the equine being of paramount importance (FEI Endurance World Championship 2021). Ilyasse El Messaoudi from Morocco holds the highest African rank in the FEI endurance open riders' world ranking, standing at 173rd. The Tunisian team secured a seventh position in the World

Endurance Championship for Young Riders and Juniors 2017. In the most recent edition of 2021, Tunisia participated with five athletes (FEI Endurance World Championship 2021). The most challenging endurance race globally is organized by Rocket Horse and traverses the stunning landscapes of the South African coast. Covering a total distance of 350 km, the race spans five days. Each rider is supported by a team of three experienced horses, and only one team can emerge victorious. This event has attracted riders from various countries, including Australia, Canada, Germany, Guatemala, Mexico, South Africa, the UAE, the UK, and the USA. In 2018, Briton Rosie Riall secured victory (Pinguet 2019).

Endurance horses must possess specific morphological and locomotor attributes that enable them to excel in long-distance races. Different breeds offer distinct advantages and disadvantages based on factors such as the breed type, duration, and climatic conditions (Ancelet 2014). Some attribute the Barb horse with the greatest endurance among oriental equines. Its unique characteristic is having a fifth lumbar vertebra, which reduces strain on the muscles supporting its spine (Angelik 2014). In endurance horse racing between 2003 and 2013, Arabian horses represented an average of 52.7% of the top 5 ranked, Arabian half-breeds accounted for 13.7%, and Anglo-Arabians contributed 8.9% of the total races.

The performance of endurance horses is significantly influenced by their genotype, which explains the diversity of physiological responses across various horse breeds. A comparative study of three breeds revealed that Andalusian horses exhibited a notably lower aerobic working capacity compared to Arabian and Anglo-Arabian horses (Castejón et al. 1994; Castejón-Riber et al. 2012). The same study demonstrated that at speeds of 15, 20, and 25 km/h, the amount of lactic acid produced during standardized field exercise was lower in Arabian and Anglo-Arabian horses compared to Andalusians (Castejón et al. 1994).

11.4.2.3 Show Jumping

Show jumping stands as the most prevalent equestrian practice, manifested through "runs" conducted within horse clubs. These runs encompass guiding horses at various gaits and navigating "show jumps." The heights of these jumps range from 0.40 to 0.90 m for ponies and 0.65 to 1.15 m for horses, with a record pinnacle of 2.47 m. Additionally, long jumps extend from 2.70 to 4.20 m, with the record stretching to 8.40 m. North African countries have participated five times in the last 18 Mediterranean Games. Notably, show jumping has been the exclusive event in nine out of the last ten editions. The most recent edition in Barcelona in 2018 featured participation from Algeria, Egypt, Libya, Morocco, and Tunisia. In the team rankings, Egypt secured the fourth position, Morocco the seventh, Tunisia the 10th, and Algeria the 12th out of 22 competing nations. Within the same competition, the highest-ranking African athlete in the individual standings was an Egyptian, attaining the third place overall (FEI Endurance World Championship 2021).

This equestrian pursuit maintained a presence in the nineteenth edition planned for Oran, Algeria. Moreover, show jumping singularly graced the equestrian events of the 12th All-Africa Games held in Rabat, Morocco, in 2019. During this edition, Algeria, Egypt, and Morocco dominated the team rankings. Noteworthy individual performances included the top three athletes from Morocco, the fourth from Algeria, and the fifth from Egypt. The FEI General Assembly, convened by the South African Equestrian Federation (SAEF), took place in November 2020. The SAEF was honored with the FEI Group IX Africa Cup, a distinction earned through the meticulously organized Penbritte Equestrian Centre event in Johannesburg from May 15th to 19th, 2019. The event showcased disciplines such as Jumping, Dressage, Endurance, and Vaulting, attracting participants from 14 African countries. Notably, Lisa Williams from South Africa emerged as the sole African contender eligible for the Longines FEI Jumping

World Cup™ Final 2019 in Gothenburg, riding her remarkable horse, Discovery Campbell (Norman 2019). A monumental achievement was witnessed at the 2018 Youth Olympic Games in Buenos Aires, Argentina, as young athletes from Egypt, Mauritius, South Africa, Zambia, and Zimbabwe combined forces to secure a groundbreaking bronze medal in the continental Jumping event (FEI Fédération equestre international 2018).

11.4.2.4 Complete Equestrian Competition

The Complete Equestrian Competition (CCE) is a multifaceted discipline that amalgamates three distinct events: dressage, cross-country, and show jumping. This discipline stands as one of the seven approved by the FEI and has held the status of an Olympic discipline since 1912. Its origins trace back to the military's requirement for resilient, robust, and manageable horses. At the pinnacle of international events in this domain is the International Complete Competition (CCI). This competition stands apart from the International Combined Competition (CIC), which remains a national event accessible to other federations. The differentiation primarily hinges on the level of the events and the intricacies of the cross-country segment. The cross-country event itself unfolds in four phases: a road phase encompassing 3–6 km at a trotting pace, a steeplechase course spanning 3.1 km with obstacles of various forms, a road phase once more, and finally, the cross-country phase.

11.4.2.5 Cross-country

Cross country serves a dual role within the equestrian realm—it can either be an integral component of eventing or stand alone as an independent test. Its core objective lies in showcasing the remarkable amalgamation of speed, endurance, and agility inherent in the horse-rider partnership. This timed event unfolds across a meticulously designed course, replete with 12–35 fixed, natural obstacles characterized by diverse profiles. The terrain itself exhibits an array of variations, further accentuating the challenge. Due to its inherently perilous nature, this discipline necessitates specialized equipment to ensure the safety of both horse and rider.

11.4.2.6 Dressage

One of the foundational stages in the training of jockeys and riders involves immersing themselves in the realm of dressage, which in itself is a distinct sport. The exercises encompassed by "dressage" serve as a platform for genuine choreography, culminating in captivating equestrian performances. The essence of dressage lies in cultivating a saddle horse's docility, instilling regularity in its gait, and enhancing its overall rideability. This discipline reaches its pinnacle in events known as equestrian shows. At its core, dressage strives to imbue any horse with qualities of obedience, consistency in gait, and an enjoyable riding experience. On the grandest stage, dressage finds its place in the Olympic Games. During this advanced level of competition, horses are capable of executing remarkable maneuvers such as the "passage," which involves a condensed trot, and the "piaffe," an elegant trot executed in place.

In South Africa, a distinct equestrian discipline known as "reining" flourishes. This style falls under the umbrella of western riding and encompasses intricate maneuvers such as backing up, pivots, sharp stops, and sliding stops. Even the tiniest of ponies hold a special role, serving as an ideal choice for children's mounts while remaining equally popular among adults within the team. Over the years, this discipline has introduced numerous generations to the joys of horseback riding, creating a lasting bond between riders and their equine partners.

11.4.3 Model Competition and Pace

Competitions centered on the evaluation of models and gaits, often referred to as "shows" for Arabian horses, provide a platform for assessing the horse's physical structure and behavior across its three gaits. Another facet of equestrian competitions involves driving, encompassing a trio of distinct tests: dressage, the marathon (a timed challenge conducted across diverse terrains), and maneuverability exercises.

11.4.4 Equestrian Games

11.4.4.1 Vaulting

Vaulting originated more than a century ago in the Tyrolean Mountains. It shares a historical similarity with the North African fantasia, both of which serve as preparatory exercises for war. Like other traditional equestrian activities, vaulting occasionally shares similarities with show jumping (INRA 2014). Despite its limited documentation in Africa, vaulting does find a unique practice ground in southern Tunisia. Here, practitioners display impressive feats such as standing on the saddle, maintaining unstable positions while clinging to the horse, relying on a lone stirrup for support, galloping upright on the horse, and even resting on the horse's head. These exercises evoke a sense of competition akin to those performed by the Cossack horsemen. Historically, vaulting was a widespread activity in various African nations during the era when horses were utilized for warfare. It played a role in preparing riders for combat. Over time, these horseback acrobatics transitioned into captivating acts within circus performances. Vestiges of this practice persist in different countries in the form of equestrian games.

An example of such a game is tent pegging, which is practiced in Sudan and South Africa. This traditional game also has roots in the Algerian Highlands, although it is gradually fading there. Tent pegging involves retrieving an object, often transformed into a target for a second rider, using a knife or by hand. In Bou Saada, a notable trial during the enthronement of young riders involved delicately lifting a bowl of honey or melted butter without spilling a single drop. The last African cup of vaulting was held in South Africa with the participation of three nations: Mauritius, Zimbabwe, and South Africa (Fig. 11.46).

Fig. 11.46 Lambert Leclezio is the first Mauritian athlete to compete at the FEI Open European Vaulting Championships for Juniors in 2011. (FEI 2012)

11.4.4.2 Polo

Polo, an ancient game hailing from Central Asia and likely originating with the Scythians, is believed to have evolved in the African continent as well. It has gained substantial popularity in South Africa, where the South African Polo Association was established in 1905, marking one of the country's oldest sports organizations. Beyond South Africa, polo is actively practiced in Egypt, Kenya, Morocco, Nigeria, Tunisia, Zambia, Zimbabwe, and Uganda, all proud members of the International Polo Federation (FIP). Established in 1982 with its headquarters in Montevideo, Uruguay, the FIP is entrusted with the management and global development of polo. Notably, it achieved official recognition by the International Olympic Committee in 1998 (FIP Federation of International Polo 2014). The sport's prestigious World Cup, hosted every 3 years since 1989, has drawn international attention. The most recent edition took place in Australia in 2017, while the last African country to participate was South Africa in 2008 in Chile.

Polo unfolds on a field measuring 275 × 145 m and is structured into 4–8 periods, each lasting 7 min and 30 s to 8 min. The game assembles two

teams, each composed of four players, who employ long-handled mallets to maneuver a ball into the opposing team's goals. In the realm of polo, horses sport shaved manes and braided tails to prevent entanglement with the mallet. Their legs are safeguarded by specialized bands, while a martingale restricts head movements. Players don helmets often equipped with grids and knee pads for safety.

In the Algerian Highlands, a similar game named "taoud" or "gaous" was historically played. This version featured two teams of ten riders on a 30-meter pitch, with goals marked by stakes on either side. Players contested possession of a wooden ball using a curved stick or a palm tree stalk, striving to propel it into the opposing goal.

11.4.4.3 Horseball

Adapted from the Argentinian sport of Pato, horseball is played on a field spanning 60–70 × 20–30 m. The game involves a ball equipped with six leather handles, which must be strategically thrown into a vertically positioned circle measuring 1 m in diameter and situated at a height of 4 m. Matches are divided into two 10-min periods, featuring teams composed of 4 players each. For the protection of the horses, gaiters shield their limbs, bells are worn on their feet, and a martingale limits head movements. Stirrups are connected by a strap to prevent saddle rotation, and players can opt to wear knee pads for additional safety. Horseball can be likened to a fusion of rugby and horse basketball, where two teams engage in competitive play, aiming to score as many goals as possible by throwing the ball through high hoops. The landscape of horseball competitions is characterized by its amateur nature, yet its popularity is on the rise, attracting an increasing number of enthusiasts. France is a dominant force in international horseball competition. The sport has also reached North Africa, Canada, the western United States, the Middle East, and select countries in the East.

Horseball remains a developing amateur sport. It has found a presence in Algeria, South Africa, and Togo. Among these countries, Algeria has joined the International Horseball Federation (FIHB) and holds the 12th position among the federation's 17 member countries. The FIHB's world ranking includes eight Algerians, with Mr. Abderaim Sad ranked 855th among the 1502 members. Despite this, the sport suffers from a lack of championships, visibility, publicity, and funding. Matches often occur within private clubs and the Republican Guard. However, the sport's inherent appeal and dynamics could position it as a key element for sporting development. In other sub-Saharan African regions, horseball tournaments are organized. For example, in September 2019, a mini-promotional tournament was hosted by the Hymane Club de Lomé in Togo. The aim was to introduce the local population to this engaging equestrian discipline. South Africa also participated in the grand horseball—pony-games—polo tournament held in Lamotte-Beuvron, France, between the 18th and 20th of May, 2013.

11.4.5 Traditional Sports Activities

11.4.5.1 Fantasia (Tbourida)

The horse holds a significant place in traditional African societies, as evidenced by practices like fantasia, a captivating equestrian art that has historical and cultural significance. Fantasia originated as a practice to bolster the combat capabilities of soldiers, resembling the North African fantasia, which served as a war preparation exercise (Figs. 11.47, 11.48 and 11.49). However, fantasia has also evolved into a popular form of entertainment, often performed during festivals like Ouaada or Moussem (veneration of the wali) and other holidays.

In the Maghrebian dialect, the term for fantasia is commonly referred to as "fantazya" or "tburida," derived from the root word "BRD," meaning "powder." In the Maghreb region, these shows are known as "laâbel-baroud" or "laʿb al-bārūd" (meaning "game of powder") and "laâbel-khayl" or "laʿb al- ḵayl" (meaning "game of horses"). These names have historical roots, and the term "fantasia" arose due to misinterpretation. The term "fantasia" is believed to have been misinterpreted by the French painter Eugène

Fig. 11.47 Fantasia parade in Mekhatria, at 10 kms north of the seat of the wilaya of Ain Defla, Algeria. (Image credit: Bisker Mohamed) (Bisker 2017)

Fig. 11.48 The Fantasia equestrian parade with warrior inspiration (Blog du cheval) (https://blog.cheval-daventure.com/fr/post/140/la-fantasia-une-tradition-equestre-dinspiration-guerriere)

Delacroix, who erroneously associated it with "equestrian show." The true origin of the word can be traced to classical Arabic, where confusion between two words built on the same trilateral verbal root, ḵayāl (meaning "imagination") and ḵayyāl (meaning "riders"), contributed to this misconception. The practice of fantasia has deep cultural ties in Algeria and Morocco, known respectively as "El Goum" and "Tbourida." Fantasia is categorized into various forms, such as Temerad and Guelba in Algeria, and Nassirya, Charqaouia, Kheyyatiya, and Heyyaniya in Morocco. There's also individual fantasia, played mostly in eastern Algeria. The essence of fantasia is rooted in its historical connection to Berber traditions of horse riding, particularly the use of Barb horses or "war horses."

The core of fantasia involves riders on richly harnessed mounts simulating a cavalry charge, firing black powder rifles in coordinated salvos. The artistry of the game is often likened to a display of strength, courage, and symbolic confrontation. This tradition represents a modern continuation of Arab-Turco-Berber horse-riding skills from North Africa. Fantasia showcases the bond between horse and rider, as Barb or Arab-Barb horses are trained meticulously for the sport. The riders and their horses execute choreographed figures with precision and coordination, accompanied by the thunderous rhythm of their galloping hooves and synchronized gunshots (Pierre 1905).

In Algeria, approximately 350 traditional equestrian associations continue the practice of fantasia, while in Morocco, around a thousand troops and nearly 15,000 horses partake in competitions organized by national stud farms during religious festivals and other significant occasions. Though the practices of fantasia differ in various regions, their common thread is the celebration of equestrian skills, history, and culture. This vibrant tradition continues to thrive, deeply rooted in the heritage of North Africa.

11.4.5.2 Traditional Horse Racing

Horse racing is a widespread practice that takes place in various regions, often serving as a platform to showcase the prowess of both the horse and the rider. Races can be as straightforward as impromptu gatherings where riders aim to demonstrate the superiority of their mounts or their own skills. Many of these races occur on open grounds, without extensive preparation, and the participation of horses is often organized through informal communication networks (Fig. 11.50). However, certain horse racing events hold traditional and celebrated statuses, such as the Sahel Festival in Amdjarass, located in eastern Chad. The Sahel Festival is an example of a renowned and time-honored event that draws participants

Fig. 11.50 Lesotho's mountain jockeys race. (Kuwait times 2022)

and spectators alike. While the dynamics of horse racing can differ across locations and occasions, the overarching essence remains consistent—a display of the swiftness and strength of horses alongside the riding proficiency of their jockeys. Whether it is a casual gathering or a prominent festival, horse racing remains a captivating and enduring expression of equestrian skill and tradition.

11.4.5.3 Horse Dancing

Among the Peuls and Wolofs of Senegal, horses held a distinct role as part of the dowry demanded from the groom. This practice might be linked to the perceived protective power of horses over the family, possibly explaining the tradition of hanging horseshoes at the entrances of homes. The "Fassu Kalifa" horse, known for its nobility, was highly sought after by both customary and religious leaders. This horse type symbolized prestige and authority, embodying a sense of nobility that resonated with traditional and spiritual figures. Additionally, a specific category of horses called "Pekh" was bred and trained exclusively for dance performances. These horses executed choreographed routines, a tradition that had been perpetuated since the time of the Cayor Empire. Victories and celebrations were marked by these captivating displays known as "fantasies." These dancing horses continue to participate in customary ceremonies, adding an artistic and cultural element to the events.

In northern Cameroon, horses maintain their significance as symbols of prestige and authority. Religious leaders, in particular, breed horses for their esteemed reputation. The coloration of the horse, particularly chestnut with four white or light gray balzanes (sock-like markings on the legs), adds to its importance. These horses are meticulously selected and trained to perform a choreography that originated with the arrival of Adama, the General of Conqueror Ousman Dan Fodio. This choreography serves to commemorate victories and achievements. This tradition is upheld across various lamidates (chiefdoms) and sultanates in Cameroon and Nigeria, underlining the enduring connection between horses and authority in this region (Mohamadou 2007).

11.4.6 Leisure Riding and Equestrian Tourism

Equestrian clubs and centers across Africa are embracing the development of circuits designed for horseback hiking or safaris, often in collaboration with tourism development agencies. Equestrian safaris offer a unique and immersive experience in countries such as Botswana, Kenya, Namibia, Tanzania, South Africa, and Uganda

(Fig. 11.51). These safaris typically involve a group of 8–10 experienced riders who embark on multi-day journeys through natural landscapes, surrounded by the magnificent African wildlife (Fig. 11.51). The safaris can either be itinerant, with camps shifting regularly, or they can involve stays in lodges or established camps. The accessibility of the horse safari varies, catering to experienced riders, intermediate level riders, families, and visitors accompanied by guides.

Certain countries, including Egypt, Ethiopia, Madagascar, Morocco, Mozambique, Senegal, and Zimbabwe, opt for equestrian hikes that span from 1 to 6 days, allowing participants to explore tourist-friendly regions and engage with local communities. Depending on the location, riders can savor the beauty of nature during bivouacs or enjoy stops at comfortable accommodations. Each day, baggage and supplies are transported to the next stop using vehicles or pack animals. It is crucial to ensure proper care and maintenance of the horses during these hikes. Some expeditions venture into remote and challenging terrains, involving steep paths and basic amenities such as portable toilets.

It is worth noting that circus riding is not a native tradition in Africa, and the horses typically used for these activities often come from European contexts. The growing popularity of equestrian tourism, hikes, and safaris contributes to a deeper connection between people, nature, and the rich cultural heritage of the African continent (Fig. 11.51).

11.4.7 Horse in the Army and Security Forces

The use of escort cavalry has been popularized by Middle Eastern kingdoms, initially as a military authority and later as a political symbol. This practice is notably visible in African political capitals, as well as in the remnants of Sultanates and Lamidates. The escort cavalry, which is often a part of the armed forces in certain countries, plays a vital role in escorting national dignitaries during protocol missions. This includes occasions such as visits from foreign heads of state, presidents, and national holidays.

Furthermore, the cavalry service of national security agencies also fulfills traditional roles in maintaining order. This involves tasks like overseeing sporting events, both national and international competitions, festivals, and responding to

Fig. 11.51 Tourism activity by riding Nooitgedacht horses in South Africa. (The figure illustrates a scene where a game warden and a tourist, riding Nooitgedacht horses, are approaching a female rhinoceros with a calf visible in the background. These South African horse breeds have demonstrated their exceptional suitability for guiding inexperienced riders during game safaris. (Photo by F.J. van der Merwe) (FAO 2002))

situations of civil unrest. The cavalry unit is also entrusted with urban patrols and the surveillance of diverse territories, encompassing forests, coasts, and more. These police officers are versatile and may be involved in missions beyond horseback, such as static guard duty or the transportation of prisoners. This multifaceted role highlights the significance of cavalry units in ensuring security and upholding public order in various contexts across the African continent.

11.4.8 Hippophagea (Meat and Milk)

The consumption of horse meat in Africa is very low and has been decreasing over time. Hippophagy, the practice of consuming horse meat, dates back to prehistoric times, although it was not widespread. In the Maghreb, the consumption of meat and milk products from horses and donkeys was known. However, due to concerns about its potential as a vector for diseases like salmonellosis and trichinellosis, there is a certain level of mistrust and various taboos associated with it—some rooted in religious beliefs and others in cultural norms. This aversion is linked to the close relationship humans have with the horse.

In fact, the closer an animal is to humans, the more it can substitute for them in rituals and sacrificial meals. Conversely, consuming animals too closely associated with humans can be seen as sacrilegious. In ancient times, horse meat consumption was considered barbaric, and the Catholic Church opposed it. The Church even prohibited it in the eighth century, possibly to counter the practices of Nordic religions. Horse meat consumption is indirectly prohibited in Judaism, as the Torah only permits the consumption of mammals with cloven hooves. According to the hadith, Islamic tradition allows the consumption of horse meat.

Supporters of hippophagy praise its qualities, extolling its exceptional meat that has historically been recommended for treating anemia. However, opponents, including animal protection associations like the Brigitte Bardot Foundation, focus on the conditions of animal transport and slaughter. They do not take a stance on consumption. Tasty horse meat has low moisture content (2–4%), is rich in iron (4–5 mg per 100 g), minerals like zinc and selenium, and vitamins (B3, B6, and B12). It contains 60–70% unsaturated fatty acids, including some that the body cannot synthesize (linoleic acid and alpha-linolenic acid), which seem to aid in preventing cardiovascular diseases.

In Africa, horse meat often comes from injured or culled animals that are no longer fit for their initial roles. Senegal is the only African country with information on horse meat production. In 2009, it produced an estimated 9500 tons, ranking 13th globally in production 180. Cameroon is known for valuing horse intestines and ascribing medicinal properties to "fired forelimbs," especially around Mount Manengouba. While horse consumption is rare, it has motivated some to breed horses (Mohamadou 2007). Mare's milk is comparable to human milk, with low lipids and high lactose. It is rich in vitamin C and contains half the lipids of human or cow's milk. Production varies by breed, averaging around 20 liters, requiring three milkings due to small udder volume. It is consumed as a drink because it does not curdle. Mare's milk and koumis, a traditional fermented mare's milk drink, are popular in Central Asia. They are believed to treat liver, stomach, and heart issues. They are also used in cosmetic products, particularly to prevent wrinkles due to their tightening effect. Ancient civilizations recognized these benefits with figures like Herodotus and Cleopatra praising them.

Breeding horses solely for meat production is generally not profitable due to their energy needs. However, interest in milk production is increasing, driven by cosmetic uses. Notably, donkey production is valuable for the Chinese market; donkey meat, known for its aphrodisiac properties, and donkey skin, used to make ejiao or "donkey skin gelatin," are sought after. This has led to a decline in donkey populations in Africa and export bans.

11.5 African Horse Diversity

11.5.1 Morpho-Biometric Characterization

According to Gaouar (2009), this method is widely used to characterize and compare breeds of farm animals (goats, sheep, cattle, camels, and horses) (Gaouar 2009). The phenotypic traits were the first traits used for the selection and the definition of the breeds. These traits result from a simple observation of the animal's characteristics, such as coat color, leg color, head and body morphology, and more. They can also include morphological measures like height, weight, and body width, as well as performance indicators such as growth rate, milk production, and hair production (Gaouar 2009).

Furthermore, the similarity of morphological characteristics can reflect genetic identity, although it might arise from different alleles or genes located at different loci. Differences in phenotypic expression can stem from actual genetic differences, but they can also be attributed to variations in expression or penetration levels (Gaouar 2002). Penetration refers to the frequency of expression of a dominant trait in relation to the number of known carriers of the gene in the population. Expressiveness pertains to the degree of intensity of a hereditary trait. These considerations limit the use of morphological characters in reconstructing breed phylogeny and characterization (Gaouar 2002). However, it is useful as initial characterization and understanding African horse heritage due to limited detailed genetic characterization research on horses in Africa. These tools are of significant importance and are gaining momentum, particularly with the emergence of methods like Genome-Wide Association Studies (GWAS).
